# **eCabinet Systems Made Easy – Learning the Software**

Easy software is simply software you understand.

If you don't really understand how it works and what you are trying to do, software can be confusing, difficult and frustrating. Once you understand, it seems easy.

In this manual we will try to develop this understanding so that eCabinet Systems is easy for you.

This understanding is especially important for cabinet design software because each software package approaches the design effort differently. If you try to learn eCabinet Systems from the perspective of another package, it will appear convoluted and difficult. If, on the other hand, you understand our approach, it will appear simple, easy and intuitive.

## The Two Approaches to Using eCabinet Systems

eCabinet Systems is a highly capable cabinet and furniture design software with a large offering of features and capability. When you distill it down, however, there are really only two fundamental functions of any cabinet design software,

- Develop cabinets and assemblies and save them in libraries
- Combine the saved cabinets and assemblies into jobs which you process and build

About 60-80% of the effort required to learn the software centers around the first function, developing your own library of cabinets and assemblies. Traditionally, you had no choice but to learn this process and develop your own libraries before you could begin processing jobs. Now however, there is a second approach. Through a program called Design Sharing, you can purchase libraries of cabinet and furniture designs from other eCabinet Systems Members who have already learned the software and developed their libraries.

This approach offers new users a short cut to actually building cabinets and furniture using the software.

There are a lot of cabinet makers that have become highly skilled using the software and have developed libraries of designs that have been built and refined over time. Now, many of these shops are offering these proven libraries to others through the Design Sharing program. Not only do you get their files, but you also get their cabinetmaking skill and experience.

These files are regular cabinet and assembly files, so you can also modify them. After awhile, you could become skilled enough that you too can develop and offer your libraries and designs to others.

If you are planning to use shared libraries, see our web site [www.eCabinetSystems.com](http://www.eCabinetSystems.com) and click on *Design Sharing* for complete details. You can review currently available libraries as well as purchase libraries at that site. Then, when using this manual, you can skip the *Cabinet/Assembly Editor* areas of the manual and immediately begin using either *Batch Input* or *Custom Layout* to create your jobs.

In addition to Design Sharing, we also offer designs for furniture created by leading professional furniture designers under a program called *The Thermwood Furniture Network*. This program works a little differently.

The actual designs are available on our web site [www.ecabinetSystems.com](http://www.ecabinetSystems.com) under *Thermwood Furniture Network*. You can download a file that installs the furniture designs on your system. This same file installs the CNC programs needed to make the complex moldings and carvings directly to a Thermwood CNC router control. This

download is free. There is however, a design fee associated with actually running the CNC programs which is used to pay the professional designer.

Should you wish to build this furniture and do not have your own Thermwood CNC router, you can find numerous machine owners that are willing to make the parts for you. They are listed under *Production Sharing* on the web site. In this case you work directly with them and not through the eCabinet Systems program.

Regardless of which approach you decide to use, you should read the overview titled *Understanding the Software*.

## Understanding the Software

If you have never used cabinet design software before, this information is important. It will give you an overview that will make the software easy to understand.

If you have used or been exposed to other cabinet design software, this information is vital. Understanding the fundamental difference between eCabinet Systems and the software you used in the past is “vital” to making eCabinet Systems easy.

There are different approaches to designing cabinets. The approach used in eCabinet Systems is different than the approach used by others.

The simplest, but most restrictive approach to cabinet design is to offer libraries of cabinets and allow the user limited ability to change certain parameters, such as size or number of drawers. Using this approach the extensive details of cabinet design and construction are fixed by the software developers who created the libraries. The only features the user can modify are those specifically allowed.

This type of software appears easy because of the limited number of things you can do with it and the fact that you can pretty much ignore the fundamental cabinet design process and simply select the cabinets you want from a library.

eCabinet Systems offers a program called Design Sharing which provides a mechanism by which power users of our software sell libraries of cabinets to other users. Those that want the simplicity of just using cabinets from a library can still work with eCabinet Systems.

We believe this approach has two advantages. First, the cabinet designs are made by real cabinetmakers. Experienced cabinetmakers will incorporate a lot of cabinet making experience into their designs that will certainly be useful to other cabinetmakers.

The second advantage of this approach is that, unlike other library programs, you can modify the design if you want. eCabinet Systems still remains a full function design package even if you choose to use other people’s libraries.

Should you decide to develop your own cabinet designs, you need a full function software that gives you control over all aspects of design and construction. Software that offers the user control over all aspects of cabinet design and construction, like eCabinet Systems, is by its very nature somewhat involved. All software that offers this ability, regardless of who supplies it, is based on a single concept. That concept is that each and every detail of cabinet construction is controlled by a parameter. Change the parameter and that particular detail changes.

Obviously this is more involved and puts more demand on software developers. The software should understand how changing one parameter affects other parameters. Some

software simply ignores interrelationships, so if you change one parameter, a back for example, you must also specifically change any other parameter that is affected, such as the top it overlaps.

This is not the case with eCabinet Systems. eCabinet Systems automatically adjusts every parameter affected when you make a change.

There are two different approaches to managing parameters. Understanding this difference is important, especially if you have used or been exposed to the other approach.

The approach used by others is to offer an area where the user defines each and every detail of cabinet construction. All parameters are displayed and the user defines his or her preference for each and specifies how conflicts are handled. This list of parameters resides in the software and defines how cabinets are created.

At this point, cabinets do not exist. Once parameters are defined, you create a cabinet by instructing the software to create a cabinet of a certain size and configuration using the defined parameters. Parameters dictate the details of cabinet construction.

Although it sounds simple, this approach has two drawbacks. First, it is difficult and time-consuming to define all cabinet parameters before a single cabinet is created. This must be done when you first install the software. This is also the time when you know the least about the software and parameters.

The second drawback is that this approach tends to make it difficult to develop and work with a variety of designs. Changing parameters back and forth to create cabinets that differ from each other is complex. Also, you must actually create a cabinet before you can see the effect of any parameter change, so users tend to make all cabinets essentially the same once they find a set of parameters that work.

eCabinet Systems takes a different approach. In eCabinet Systems you DO NOT EVER create cabinets. Cabinets already exist. You modify, duplicate, and save them using new names but you do not create new cabinets from scratch.

In eCabinet Systems, the list of parameters is part of EACH CABINET not part of the SYSTEM. Although this sounds like a simple difference it has profound impact on how the software functions.

Instead of specifically defining parameters for each cabinet, existing cabinets already have parameters. To obtain a different design, the user modifies the parameters they want changed, leaves the others alone and saves the result under a new name.

The key ingredient to the eCabinet Systems approach, which really characterizes the software, is the ability to display highly detailed, accurate three-dimensional graphic images of the cabinet, including all joint and part detail while you are adjusting

parameters. These images show exactly what the cabinet looks like with the current parameters. Changing a parameter causes the image to change, so you can examine the result.

This image can be moved, rotated, exploded and zoomed. Components can be hidden, made transparent or turned into wireframe. In short, the user can examine in minute detail the actual effect on the cabinet of any parameter change.

You start with a standard cabinet from a directory called “Standard Cabinets” and modify parameters until you fashion a cabinet designed the way you want. This new cabinet is saved under a new name in a new directory. The original cabinet still exists in the old directory under the old name.

The new cabinet can then be loaded, further modified and saved under yet another name. Now you have three, the old cabinet, the new cabinet and the modified version of the new cabinet.

This approach makes development of entire libraries easy and yet provides almost total flexibility.

To develop a library, start with a standard cabinet. Change it to include the parameters you want to be shared by every cabinet in your new library. Save this in a new directory as a “seed” cabinet.

Now, load this seed cabinet, resize and modify it to the first cabinet you want in your library. Save it. Load the seed cabinet again, fashion and save your next cabinet. In a short time you have an entire library of cabinets that all share the same characteristics as your seed cabinet.

Should you need to change any of these for a specific application, it is easy because the parameters reside with the cabinet, not the software. So, exactly how do we change the cabinet parameters?

To help understand, we might want to separate changes to the cabinet into three categories, size, configuration and parameters.

Size is well, size... height width and depth. This is changed on the *Main* page of the *Cabinet/Assembly Editor* but can also be changed whenever the cabinet is used in a job.

Configuration includes shelves, partitions, face frames, moldings, doors, drawers, etc. The configuration of a cabinet is developed through a series of Editors that are reached from the *Main* page or on the top toolbar.

The *Editors* use the concept of *Default* components or settings. This means that many details such as door design, drawer front and drawer box design, pulls and moldings have a “Default” selection so that they do not need to be selected each time they are used.

When one of these components is added to a cabinet, the current “Default Selection” is automatically used; therefore using a specific design is a two step process. First, the design is located and designated as the “Default” generally using a *Set Default* button. Then, Then the item is added which automatically uses the “Default” selection.

Parameters are the little bitty details concerning everything about the cabinet. Material, joinery, fits, insets, and about everything else. These parameters are adjusted in an area called *Construction Settings* that is also reached from the *Main* page of the *Cabinet/Assembly Editor*.

There are actually two kinds of parameters, which can cause some confusion. Some parameters, a *back inset* for example, affect the cabinet as soon as they are changed. Other parameters define how items, a shelf for example, are added to the cabinet. Changing this second type of parameter doesn’t change existing shelves, it only affects shelves that are added after the change. Of course, to make it even more confusing, if you highlight a shelf and then make a parameter change it changes the shelf that was highlighted.

This is done for a good reason. It allows you to add multiple shelves and make each different. Add the first, change the parameters and add a second. The second shelf has the changed parameters. Change the parameters again (in doesn’t affect existing shelves) and add a third shelf. It is now different from the other two.

Each area that has this “add” feature has this same capability.

Despite this small bit of complexity, it’s actually pretty simple. Change size on the *Main* page or when you use the cabinet, change configuration using Editors and change parameters in *Construction Settings*.

Regardless of how many configurations and parameters the software allows for, cabinetmakers will always want to do something more. To address this, a *Part Editor* is available. Using the *Part Editor*, any part of the cabinet can be cut, pocketed, profiled or machined. This lets you create almost anything you can imagine.

The system also lets you import DXF files from other CAD systems and use them to either make parts or to cut or pocket their shape into a part.

The amazing thing is that all of these creations can be actually machined on a Thermwood CNC router from the file created by eCabinet Systems software. You can cut and profile individual cabinet parts pretty much any way you want.

If you want to put an edge profile on a part in the software, you need a tool file with the correct profile.

Tool files are available within the software for the profile tools that can be purchased through the eCabinet Systems program. There are also some sample files for asymmetrical tools that work well for making MDF doors.

You can also develop a tool with your own custom profile. This tool is developed in an area called a *Shape Manager*. Tools developed in the *Shape Manager* are used in the *Part Editor* to cut a profile on a part.

An interesting note about this feature is that once a profile is placed on a part in the *Part Editor*, that profile can be machined on a Thermwood CNC router, even if a custom profile tool for that shape is not available. The Thermwood control can create a modeling program using a ball nose and corner bit to machine the profile edge using modeling techniques.

If you are designing a part that is used on a cabinet that may change size, you will need to define how you want the size and position of the machining operation to behave as the part size changes. This is done in an area called *Constraint Manager*". You define "constraints" and then see how it reacts as the cabinet size changes. You then adjust the "Constraints" until you get what you want.

So far it has been pretty simple but now we are going to add a valuable feature that can make it a bit more confusing if you don't understand it. It has to do with the word "Assembly" in *Cabinet/Assembly Editor*.

A lot of complex cabinets and furniture cannot be defined with a single set of parameters. The approach eCabinet Systems uses to create these more complex pieces is to allow multiple cabinets to be loaded into the *Cabinet/Assembly Editor* at the same time and saved together as an "Assembly". This approach is very powerful, but can be confusing. Let's look at an example.

Suppose we need an upper island cabinet with a face frame and doors on both the front and back. We need to remove the back and put a face frame and doors on it.

In designing software to allow for this, you could create parameters for a face frame and doors on the back, but then someone will want it on the side. There are thousands of these variations and you simply can't make parameters for everything or the software would really get confusing. Instead, eCabinet Systems allows you to combine elements from two or more cabinets into an Assembly.

In this case, we take our first face frame cabinet and remove the back. Then we take a second copy of the cabinet (we can copy and paste it right there) and remove everything except the face frame and doors.

At this point the software sees two cabinets, one without a back and one without everything except the face frame and doors. Move the face frame and doors from the second cabinet to the back of the first cabinet and we have the assembly we want. It looks

like a single cabinet with a face frame and doors on both ends but we know that, as far as the software is concerned, it is actually two cabinets, each with parts removed.

We can address and change the parameters of either cabinet by highlighting it and accessing *Construction Settings*.

This is an important concept because this simple approach allows for almost unlimited flexibility and still offers the ability to address and adjust every aspect of every cabinet involved.

There are a couple of other areas we should mention in this overview. You can associate hardware, hinges, pulls, slides, etc. with a cabinet. When you do, the mounting hole pattern for the hardware is automatically added to the appropriate cabinet part. If you process the nest through a Thermwood CNC router, these hardware holes are automatically machined into the correct components.

In addition, the required hardware is added to a report called a "*Buy List*". The *Buy List* contains everything you need to buy for the job.

As a bonus, you can buy everything on the *Buy List* through the eCabinet Systems program using the software. These sales fund continuing software development so you are actually helping yourself if you buy your components this way.

There is more to designing cabinets and assemblies, however, these are the important basic concepts. We cover all the detail capabilities in the *Cabinet/Assembly Editor* area.

While you can generate reports such as *Cut Lists*, *Buy Lists* and *Cost Sheets* (cost estimates) for a single cabinet, most want to combine multiple cabinets and assemblies into Jobs.

Within eCabinet Systems, you do not specifically create a Job. A Job is automatically created when any one of four events occurs.

- A cabinet is placed in the Job using *Batch Input*.
- A wall is created in *Custom Layout*.
- An item is placed in the *Shopping Cart*.
- A cabinet or other entity is placed in the *Drawing Editor*.

The reason this is important is that once a Job is created, it and everything around it can be saved as a Job (.esj) file.

We have two approaches for combining multiple cabinets into a Job.

The first approach applies to shops that build essentially standard cabinets in batches. This area is called *Batch Cabinets* and allows you to simply add a quantity of cabinets to

the job by selecting them from your library. When all the cabinets have been added, you generate the reports and manufacturing output for the entire batch.

As we said, as soon as a cabinet is added using *Batch Input*, a Job is created and it can be saved as a Job file. At this point you can also run all the manufacturing reports for all the cabinets in the Job.

The second approach, and the one used by most custom cabinet shops, involves creating a room and installing cabinets from your library in that room.

In eCabinet Systems these functions are developed in an area called *Custom Layout*. Rather than combining all functions in a single *Custom Layout* area, the software uses four connected areas that make up the *Custom Layout* function.

The *Main* area is used for viewing the layout. You can tilt, rotate and zoom the room so that you can view it from any perspective. You can hide walls if they are in your way. The only thing you can do in this *Main* area, other than look at your layout, is to adjust the texture on the walls and floor.

Before you can view a room you need to actually create one. This is done in an area called a *Wall Editor*. Individual walls are created and the height and slope of the top of the walls are adjusted. Openings are cut into walls or sections added to walls in this area.

The *Wall Editor* works with entities called *Wall Lines*. These are simply lines that define the room.

Once you have a room, you will want to install cabinets. This is done in an area called *Detail Room*. This area is a little more rigid than the *Main* viewing area, but from either an overhead view or a wall elevation view, you load cabinets and then move them into position. There are several modes for doing this that you will need to learn and understand.

This area is actually quite involved and there are a lot of tools and techniques that can result in highly realistic representations of a finished room.

From the *Main* area, there is also a feature, called *Presentation View* that lets you create photorealistic views of the layout including shadows and reflections. These remarkable images are a major selling tool that have helped many shops sell their proposals, at times successfully selling against other bids that were priced lower. The highly professional image that this feature provides can be a great sales aide.

From either the *Cabinet/Assembly Editor* or *Custom Layout*, you can take cabinets, assemblies, walls and entire layouts into a *Drawing Editor*. Here, dimensioned line drawings are developed. This area also supports dimensioned isometrics and dimensioned, exploded isometric drawings.

Once the layout is complete, you can generate a *Cut List*, *Buy List* and *Cost Sheet*. If you plan to cut the part using traditional methods, you can generate a nest diagram, individual sheet diagrams, individual part drawings and labels for each part.

If you plan to run this job on a Thermwood CNC router, you can send the file directly to the control where it will be nested and machined.

We have mentioned *Cost Sheets* several times so now is a good time to get an overview of the cost estimating features of the software.

The system uses information from three areas to estimate job costs and there are two different approaches to developing these estimates.

The first input to the cost estimate is material cost. When you design a cabinet you specify the material to use and its cost. You also specify an estimated yield, which the system uses until you nest the job. Once the job is nested, the system knows exactly how much of each material is needed, the exact yield and exactly how much the material for the job will cost.

The second input to the cost estimate is the cost of components and hardware that must be purchased for the job. When you design your cabinet, you can associate the correct components with it. Since these components can be purchased through the eCabinet Systems program, the system knows the actual cost of each item and this cost is added to the material cost for the job.

The final cost elements that must be accounted for are labor and overhead. These costs are calculated from data that you supply about the cost structure of your shop. Using the information you supply, there are two different approaches to estimating labor and overhead.

The first approach uses historical ratios. It determines what the cost ratio for labor and overhead as compared to material has been in the past and applies these ratios to the new job. This approach works for shops that build a fairly consistent product line. If you build pretty much the same cabinets over and over, this simple approach should work well for you.

The second approach to estimating labor and overhead is to assign a certain number of labor hours to each cabinet and then assign a cost per hour to these labor hours. The system adds up the labor hours for all cabinets in a job and multiplies this by the cost per hour. The software allows for several different categories of labor, each at a different cost per hour, allowing for an even closer estimate.

To estimate overhead using this second approach, an overhead cost per hour is multiplied by the total number of hours in the job.

In the detail application of these estimates, additional tools are offered that can account for incidental costs such as shipping, scrap and the like.

This can be an important tool. Once the basic information has been entered, cost calculations are pretty much automatic. You can display a running total of the job cost across the bottom of the screen and a *Cost Sheet* can be generated in a second window pretty much any time you want.

Several ancillary but important tools are also available in the software. These include an image control that is used to enhance jpeg images that can be captured from many areas of the software and a *Display Part Editor* where sophisticated textures can be placed on three dimensional objects which can then be added to cabinets or custom layouts.

Another ancillary feature is a *Proposal Writer* which is used to quickly create a professional sales proposal. This very quickly generates the basic proposal which can then be exported to Microsoft Word and further customized.

There is an area called *Settings/Preferences*. As its name implies, this is an area where you set parameters that define how the software functions. This is where you tailor its “look and feel”.

The final area we will touch on in this introduction is the *Shopping Cart*. This is where you can purchase virtually anything you might need directly from major industry vendors. The *Shopping Cart* is part of a Job and each Job has its own *Shopping Cart*. As we said earlier, the software automatically adds contents of the *Buy List* to the *Shopping Cart* (unless you tell it not to) but in addition, you can browse an extensive catalog of parts, components, machines and tooling that you can purchase at Member discount pricing.

You might note that as you work with the job and change things, the *Buy List* automatically accounts for the changes as does the *Shopping Cart*. Whenever you access the *Shopping Cart*, the contents reflect the current composition of the job.

And that is a general overview of eCabinet Systems software. There are a lot more details, but before you deal with these details, it is valuable that you understand just what we are trying to do in each area and how we get the overall job done.

## Selling Libraries of Your Designs to Other Members

Once you have become proficient with cabinet and furniture design and have created your own libraries of designs, you have an opportunity to sell these designs to other Members through a program called *Design Sharing*, further enhancing your profits.

This can be especially nice when you create and build a unique design for a client. Once complete, you can incorporate your experience into the design and offer it to others, potentially creating an ongoing revenue stream that continues beyond the initial job.

The program begins by you preparing and submitting a design or library of designs. These are then offered for sale to other eCabinet Systems Members on our web site. Any sale of these designs is split equally between you and us. In addition, if any items are purchased through eCabinet Systems from your designs, you receive 10% of the margin generated by these sales.

There is no cost to submit the design library. The library remains in the offering indefinitely unless, (1) you request that it be removed, or; (2) there are no sales of the library for a continuous 24 month period. Also, those that buy your library can rate it and can also write a review. Both the rating and reviews are then made available to prospective new buyers.

There are several requirements for designs. First, the design must originate from the *Standard Cabinets* directory. You cannot modify a design developed by others and submit it as your own.

When a design is submitted, it is tagged with the name of the developer. This tag remains with the file regardless of how much it is modified. Once a file is tagged, it cannot be changed. It remains the design of the original developer. Therefore, you must begin with cabinets from the *Standard Cabinets* directory to be sure that the original cabinets you are working with have not already been tagged for someone else.

You are free to set a price on your offering, however, there is a minimum price which is either \$10 or \$1 per cabinet or assembly, whichever is greater. Beyond that you are free to set whatever price you like, however remember that the price you set is the price for the library and we will equally share any sales at that price. Set your price accordingly.

Prior to submitting a library or design, you should visit our web site and see how libraries are offered. This will help you determine how you want to present your offering to get the maximum sales impact.

Libraries are prepared within eCabinet Systems software. The system begins by retrieving the latest input dialog from our server (you must be connected to the web for this). Using this dialog, you select directories of cabinets or assemblies, jpeg images and input descriptions. The software then combines all these elements into a single file which

## eCabinetSystemsMadeEasy

is saved on your computer. You must then copy this file to a CD and mail this CD to us. We then use this CD to input your offering into our server.

In selecting cabinets and assemblies to include in your library, you will be asked to specify the “directories” you want to include. Every file in these directories will be included in your library so the first step is organizing the particular files you want into specific directories.

## Obtaining Cabinet, Assembly and Furniture Designs From Others

There are two approaches to establishing a library of cabinet and furniture designs. You can design your own or, you can obtain designs from others. There are two programs under which you can get designs from others, *Design Sharing* and the *Thermwood Furniture Network*. Each works differently.

*Design Sharing* is a program under which experienced users create and sell libraries of designs to others. Working within the software, libraries are developed, packaged and submitted on a CD. This CD is used to add the library to the *Design Sharing* offering. Others then review and purchase these libraries on our web site (go to [www.eCabinetSystems.com](http://www.eCabinetSystems.com) and select *Design Sharing*). Purchase is via credit card and we split all fees with the developer. Also, should a cabinet or assembly generate sales of components or material through the program, the developer of the library receives an additional fee of 10% of the margin on those sales.

The second way of obtaining designs from others is the *Thermwood Furniture Network*. In this program, professional furniture designers create unique designs for the program. These designs are converted into assembly files that can be used within eCabinet Systems. These designs can be downloaded and used within the software at no cost.

These designs generally are more complex and involved and use unique components such as carvings, moldings, legs, posts, etc. We have created CNC programs for each of these components that can be rented by anyone with a Thermwood CNC router. Rental of these programs is used to compensate the professional designers.

For those who do not have a Thermwood CNC router, there are shops on our web site (click on *Production Sharing*) that will make these parts for you. Beginning with Version 5, these carvings, legs, etc. can be scaled in the software, that is, their size can be adjusted for specific applications. The CNC programs can also be scaled to actually produce these parts. You are free to use these components in your own designs, even in designs you offer through *Design Sharing*, since the designer is automatically compensated whenever a CNC program is rented. The only thing you are not allowed to do is produce these components through an alternate source without paying the design fee.

More information about each of these programs is available on our web site.

## What is New in Version 5

For those that have been using earlier versions of the software, the following areas have been added or modified in Version 5.

If you have not been using the software previously, you can skip this section because it will not mean anything to you. If you are familiar with the software however, this section will guide you to those areas that are new or modified in Version 5.

In most cases, Version 5 additions are documented in this manual with the addition of new sections although, in some cases these additions were also incorporated into existing sections. Here are the changes in Version 5:

- **MDF Doors** – a new area has been added to the *Door/Drawer Designer* to design MDF doors and drawer fronts.
- **Stretchers and Braces in Cabinets** – a new area allows the addition of stretchers in cabinets with full joint capability. These can be left to right, top to bottom or front to back, pretty much any size, any position and angle. This area is used for nailers, sleepers, braces, supports, etc.
- **Allow Changes in Cabinet Size Without Losing Part Editor modifications** – an area called *Constraint Manager* has been added so you can define how modifications you make in the *Part Editor* change as the cabinet size changes. This means you no longer lose *Part Editor* data when the cabinet is resized.
- **DXF Import** – we have added the ability to import DXF drawing files into the *Shape Manager*, the *Contour* area of the *Part Manager* and the *Line Drawing Editor*.
- **Create a Part from a Closed Contour in the Part Editor** – previously, a closed contour could be used to pocket or cut through a part in the *Part Editor*. Now, the closed contour can be the actual part, cutting away everything that lies outside the contour.
- **Easily Add Countertops** – a new area reached from *Custom Layout* provides a quick interface for adding countertops. Countertops, backsplashes and waterfall front edges are supported in this area. These countertops can be taken from *Custom Layout* to the *Part Editor* where virtually any modifications can be made.
- **Drawer Boxes** – a new *Drawer Box Designer* has been added where drawer boxes are designed and saved. These can have any of the standard joints plus a new dovetail joint that can be machined on a CNC router. Drawer boxes can be added to the cabinet with a drawer front in the *Door/Drawer Front Editor* or they can be added to an opening in a cabinet using a new *Drawer Box Editor*. Drawer boxes can be installed behind doors and these drawer boxes automatically resize with the cabinet.
- **5 Piece Doors now in Cut List** – using either Thermwood doors or, a new *Build in House* feature for Conestoga doors, a new dialog allows you to define how you build 5 piece doors and then provides full *Cut List* support.

- **Edit from Batch Input** – you can now take cabinets or assemblies to the *Cabinet/Assembly Editor* and modify them directly from *Batch Input*.
- **Use Excel Spreadsheet to Load Batch Input** – the ability has been added to create a batch directly from a properly formatted Excel spreadsheet.
- **Scale Display Objects** – the ability has been added to scale or change size of *Display Objects* including applied carvings.
- **Machine Carvings into Existing Cabinet Parts** – the ability has been added to machine an inset carving into a cabinet part. You can also scale the carving to an appropriate size for the part.
- **Add Edge Banding to Any Part** – a new *Edge Banding Editor* has been added that supports placing edge banding on cabinet parts. Different banding can be placed on different edges and overlap in the corners can be controlled. Edge banding data is provided in the *Cut List* and on part labels.
- **Presentation View Settings have been Enhanced** – it is now possible to display and modify current settings for each item in the *Presentation View* by right clicking on the item.
- **Backup/Restore Feature Added** – the ability to quickly and easily backup and restore all system data files has been added.
- **Design Sharing Submission Process Added** – you can sell your libraries of cabinet and assembly designs to other Members through the Design Sharing program. An area has been added where you prepare a library for submission. The entire submission is combined into a single file that you burn to a CD and submit.

## Backup/Restore Data Files

You can save your current state of eCabinet Systems along with data files using the *Backup/Restore* capability accessed through the *File* menu.

There are two steps in backing up data. First, we need to define *Backup/Restore Settings*, then we actually perform the backup or restore process.

Select *File - Backup/Restore Settings* from the top menu. This opens a backup dialog.

In the top box, specify a directory where you would like the backup data stored or retrieved from.

Most areas in the software store data in specific directories so the backup utility can easily locate these files.

Three areas, however, allow you to store data in a directory of your choice. These are jobs, tool files and drawer box files. The backup utility assumes that, for each of these, all files are stored in a directory tree below a single parent directory. You need to specify the parent directory for each of these in the input boxes provided. In this way, the system can find all the files that need to be backed up.

Next, using the checkboxes, specify which files you want backed up.

Check the box if you want the backup directory cleared at the beginning of a backup process.

A second check box authorizes the system to overwrite existing files with the same file name during the restore process. If this is not checked, you will need to authorize this overwrite for each individual file during the restore process.

Once *Backup/Restore Settings* have been adjusted, you can backup your data by selecting *File - Backup My Files* from the top *File* menu selection.

To restore your data, simply select *File - Restore My Files* from the top file menu.

Once you restore data, you **MUST** shutdown and restart eCabinet Systems to complete the process.

## Moving Design Files between Systems

In eCabinet Systems, cabinet designs and assemblies are individual files that contain all the information and data support including textures, images, etc. You can exchange designs by simply exchanging these files.

In order to be able to transfer a design by simply transferring a file, all data concerning the design, regardless of how it is stored in the system, needs to be included in the file. This information must then be integrated with the new host system in an orderly manner.

For most cabinet data, the transfer between systems is relatively easy as many areas, door design for example, use standard design elements that are the same for all systems. The one area where this is not the case is *Materials*.

Each user defines their own sheet stock material and the chances of two independent systems having the exact same material definitions are unlikely. When you load a cabinet design from another system, it is quite likely that you will need to attend to material differences.

The material specified for the incoming cabinet may not be available on your system or, perhaps the name specified is available but it is not correct. In either case, the system will alert you to the discrepancy and offer methods to resolve the conflict.

The only specification actually checked by the system if the material does exist is the thickness. If the material exists in the receiving system and it is the correct thickness, it is accepted. If the thickness is not correct, the material is rejected and a conflict established.

This also means that if the material exists in the proper thickness but the color or texture is incorrect, it will be accepted and the surface texture that exists on the receiving system is used.

To prevent these types of problems, it is best if the parties exchanging designs communicate about material specifications and agree on the proper handling of materials.

In the software, when a material conflict arises, a resolution dialog appears. From this screen, there are basically two choices. You can add the material from the cabinet you are importing to your material list as it was defined by the person that developed the design or, you could substitute a material you currently have defined for use in the cabinet. The system will only offer you selections for substitution that are the same thickness as the material in the cabinet design.

Another possibility is that a material exists in your system that has the same name as the material used in the incoming cabinet. In this case, if the system will check the thickness and if it is the same, the material in your system will be used.

If the material name is the same but the thickness is different, you are again given a choice to resolve the conflict.

You can change the thickness of the material defined in your system to match the material on the incoming cabinet. This will work for this one cabinet, however, the material thickness of this material for any cabinets you previously saved that used this material will be wrong. When you load the other cabinet, the conflict will be detected and you will again be given this choice. If you change the thickness back, you will have the same problem when you load the new cabinet again.

The second, and better choice, is to substitute an existing material of the proper thickness for the material currently specified for the cabinet.

Another area where conflict can occur is with hardware hole definitions. An incoming cabinet may include specific hardware, a drawer slide for example. This drawer slide may also have a hardware hole pattern associated with it. The system in which it is being loaded may, however, have a different hole pattern associated with this particular slide. Thus, a conflict exists as to which hole pattern to use.

If you are importing the design to build it yourself, you may very well want to use the hole pattern you associated to the slide and not the one coming in with the cabinet. If, on the other hand you are going to machine parts for someone else, you will want to use their hole pattern and not yours.

To accommodate both of these requirements, the software uses the hole patterns associated with the cabinet but, you can change these to your default patterns after the cabinet is loaded. Simply go to the *Door/Drawer Editor*, highlight the appropriate drawers and select a new default. The highlighted parts are changed to your hardware hole pattern.

The ability to easily exchange cabinet and assembly files opens some very interesting possibilities. The developers expect that programs will develop within eCabinet Systems for Members to share designs in an effort to help one another, but we expect the idea to evolve much farther.

# Settings Preferences

## ***Settings Preferences***

There is an area in the software called *Settings/Preferences* where you specify fundamental software settings and your preferences for how you would like certain aspects of the software to work. In general, these settings can be changed any time.

*Settings/Preferences* is accessed through an icon on the top toolbar. Let's examine what we can control.

## ***Dimension Display and Input***

*Dimension Display* defines how the software displays dimensions. This selection affects dimension display everywhere, including dimensioning on line drawings. There are five choices.

Although you must select one format for display, you are free to use any format to enter dimensions. You must use the proper syntax including the foot ('), inch (") and millimeter (mm) symbols when entering dimensions. If you don't use symbols, the system will assume inches (") if you have selected any of the English formats for display or millimeters (mm) if you have specified Metric.

If you think about it, this can be quite helpful. If you are working in inches and have to enter a dimension in millimeters, you don't have to do any conversion. Simply enter the number with an *mm* after it and the system will understand.

You should note that when working with fractions, for both input and display, the system only accepts and displays fractions down to 1/32 inch. Displays are in 1/32 inch or higher fractions and all measurements are rounded to the nearest 1/32 inch. If you need tighter dimensions than this, use the *Inches and Decimal* display.

Also note that when working in certain areas such as doors or drawer boxes, vendors only offer product in specific fraction increments, 1/32, 1/16. etc. In these cases, the software automatically rounds the number so that it matches the product that is actually available.

There is one more feature that is not well documented within the software itself for dimension input but is quite useful and that is math operators. Let's say you don't know the exact dimension you need to enter but know it is the sum of three numbers. Instead of adding the numbers together and then entering the sum, just enter the three numbers with a plus sign (+) between them and the system will do the math for you. This also works with minus (-), divide (/) and multiply (\*). The system also understands the use of parenthesis.

## ***Language***

The software was written to function in multiple languages although we currently support only English. There are third-party efforts to translate the software into other languages and when complete, every portion of the software will function in the selected language. This includes titles, buttons, controls, guide boxes, Area Overviews, and error messages.

## ***Controlling Learning Mode Display***

The software includes a *Learning Mode* which pops up guide boxes when you pause the cursor over a control or menu selection. These boxes contain valuable guidance. You can turn off the *Learning Mode* by unchecking *Learning Mode*, but we do not recommend turning it off, even for highly experienced users.

If you absolutely don't want the pop-up boxes popping up, set the delay to five seconds or so. It is common for the programmers that actually developed the eCabinet Systems software to refer to the guide boxes to refresh their memory about certain features. If they need this help, almost any user will need it also.

*Zero Delay for New*, when checked, pops up any guide box that has changed from the last version of the software without a delay. If you have been working with earlier versions of the software and are familiar with the information in the pop up guides, this feature will be especially useful. When checked, any pop up guide that is either new or changed from the previous version will display immediately when the cursor moves over it. It also displays with a blue background to distinguish it from the standard guides which are tan. Once you have become familiar with the changes and new items, you can uncheck *Zero Delay for New* and all pop ups will follow the delay you set and will be tan. If you are new to the software you can uncheck *Zero Delay for New* since everything is new to you.

The next two check boxes apply to the *Cabinet/Assembly Editor*. The first checkbox turns on and off a display feature in the *Cabinet/Assembly Editor*. When turned on, pausing the cursor over a cabinet component displays a pop-up box that gives you detail about the part, including name, material and size. This is quite useful as you will find, and should normally be left on.

The second checkbox turns on and off an auto-rotate function in the *Cabinet/Assembly Editor*. When turned on, if you rotate the workspace and release the mouse button while still moving, the workspace and everything in it will rotate continuously. This is an interesting effect for a computer left unattended or for a show or to show off to a customer.

## ***Settings to Help the Software Run on Slower Computers***

eCabinet Systems is a rather sophisticated software that is graphic intensive. It uses sophisticated graphic images to display effects of parameter changes on cabinets and to aid in the layout and creation of a room. These graphic features require, above all else, a powerful graphics card. The capability of the graphics card, probably more than anything else, defines how well the software will function on a particular computer system. Since older, slower systems can have problems, we have provided some tools to try to help. In the long run, however, if you are going to use this software to run a business, you should get the best computer system possible.

The first tool is the *Level of Detail* setting. This sets the amount of image detail that is displayed in the *Cabinet/Assembly Editor* and in *Custom Layout*. A lower *Level of Detail* renders faster but with reduced image quality. It makes less demands on the graphics card and can help slower systems perform better.

There are some additional tools in the *Custom Layout* area that work in conjunction with a lower *Level of Detail* setting. Instead of simply reducing the amount of detail shown on everything, these controls allow you to completely hide those items that slow computer processing in *Custom Layout*. The *Level of Detail* setting, however, is still important and is the only tool you have in the *Cabinet/Assembly Editor*. We recommend that you set the *Level of Detail* to the minimum level needed to give acceptable performance in the *Cabinet/Assembly Editor* and *Custom Layout*.

There is one other important point that affects performance when running eCabinet Systems. Since the software makes substantial demands on computer resources, it is best to run it alone and shut down all other programs while using eCabinet Systems. This frees all available computer resources for the demanding task. Also, if you work on the Internet very much, it is likely that some of the sites you visit will install small programs on your system to report information back to them. Each of these programs uses resources and it is common to have dozens if not hundreds of these running. It is important to remove these on a regular basis.

There are several good programs for doing this and some of them, such as Ad-Aware are available free. The ones you pay for tend to have more features and do a better job of keeping your system clean. It is important, however, to minimize the number of background tasks running if you want to get the best performance from your system.

For anyone using an nVidia Quadro-series graphics chip, a “tweak” utility is available for download in the forum section of the eCabinet Systems web site. This utility may boost frames per second video performance in the cabinet editor, room layout, and other 3D areas by two to four times.

It appears that as the Quadro driver defaults from nVidia, is not optimized for

performance in eCabinet Systems' 3D areas. Also with this optimization, anti-aliasing can be enabled with little affect on performance.

This utility does not work with nVidia GeForce or ATI Radeon cards and we do not have utilities for these. It appears that these drivers are already tuned as good as possible for OpenGL.

To use this Tweak Utility:

1. You must be running Windows XP. You should not be running Windows XP 64-bit edition; it's not been checked for compatibility.
2. You must be running a late-model nVidia Quadro chip, specifically the Quadro FX series.
3. You must have 128MB or more video memory.
4. You must be running nVidia's ForceWare version 67.00 or higher.
5. You must not be using an nVidia Quadro FX Go 770 128MB; problems exist for this laptop GPU.

This Tweak Utility does NOT do a conditional check for Windows XP, so it is up to each of you to ensure that you meet the criterion. Check the web site for more information.

## ***How to Define Materials***

As you work with the *Cabinet/Assembly Editor* and certain aspects of *Custom Layout*, you will be asked to specify what material certain components are made from. The choices you are offered in each of these areas come from *Define Stock Materials* right here in *Settings/Preferences*. When manufacturing reports are generated, material requirements are determined by type of material. The system will add up all the parts made from a particular material and tell you how much of that material you need.

There are several types of material that are each handled differently in the software.

- *Countertop Stock* is used for adding countertops to cabinets when laying out a kitchen in *Custom Layout*. In the current version of the software this material is only used to display the countertop and the cost calculation and cut listing of the material is not yet supported.
- *Banding Stock* is used to put edge banding on a cabinet part, slab door or slab drawer front. The system will track the amount of banding of each type needed for a job and display this in the *Cut List*.
- *Sheet Stock* is used to make cabinet parts. This is the material that the nesting feature works with. Parts made from sheet stock are nested on the sheet sizes specified here. If you need to nest parts on solid wood boards, you need to enter them as sheet stock (using the actual board dimensions) so parts can be nested on them. This is common when making drawer boxes from solid wood.

- *Board Stock* is primarily used for face frames but can also be used to make miscellaneous parts using the *Display Board* feature.

Some generic materials are already defined in the software. The seed “Standard” cabinets are made from these materials. You can start working with the software without defining additional material, but you will need to add your particular material before you can begin doing serious work.

The *Image* selected when you define a material is the texture used to display all parts made from that material. If you change the image here, it will change for all cabinets that use this material.

If you are going to use the same actual material but finish it differently, you have a couple of choices. If an entire *Job* will have the new finish and it will be processed as a *Job*, you could create a new material with the same parameters except the *Image*. In this case, the system will nest together all parts made from this new material.

If you have cabinets with different finishes in the same *Job* and you want to nest all the parts together, the only way to handle it currently is to use different materials, each with their own image, to display the layout and then change material so they are all the same before generating the manufacturing output. The software offers a function that allows you to change material in the *Custom Layout* area rather easily.

*Board Stock* is the material used for face frames. *Board Stock* is given an *Image* here and this *Image* is used to display the face frames unless you check *Common with Door* under *Display Finish* on page 2 in the *Face Frame* area of *Construction Settings*. These are found in the *Cabinet/Assembly Editor* and these selections are made when the cabinet design is being developed. If it is checked, the face frame will be displayed with the same *Image* used for the doors instead of the *Image* selected here. Thus, using this setting you can have face frames with the same finish as the doors or with a different finish.

*Banding Stock* is always displayed with the *Image* selected here.

*Banding Stock* is used whenever edge banding is needed. Edge banding is applied to cabinet parts in the *Edge Banding Editor* and is applied to slab doors when they are defined in the *Door/Drawer Editor*. In each case, the underlying part is reduced in size to allow for the thickness of the edge banding, resulting in a part that is the proper overall size after the edge banding has been applied.

To create a part where the banding stock is the same texture as the part itself requires that the *Banding Stock* defined here be given the same texture as the part.

The ability to put a different texture on the *Banding Stock* than the part opens some interesting possibilities. You can define a relatively thick edge band which is more of an edge frame. This could be textured differently, creating an interesting design. This can be especially useful when building slab doors and drawer fronts.

It is important that the price be properly input when defining material, paying attention to the unit you are pricing.

*Sheet Stock* is priced Per Sheet.

*Board Stock* and *Banding Stock* are priced Per LINEAL Foot. Note that this is NOT per board foot but per LINEAL foot. You will find more detail about inputting material pricing in the section “Setting Up for Cost Estimating”.

## ***Setting Up for Cost Estimating***

eCabinet Systems includes a sophisticated system for estimating costs, however, to use it you must define your shop costs and select the cost estimating method you want to use. This information is defined in *Settings/Preferences - /Define Costs*.

Cost is defined by three categories, material, labor and overhead.

Material is calculated by the system using material costs you enter in the *Define Materials* area adjusted by factors you set here. Material cost also includes any hardware or other components associated with cabinets in the job. These are valued at the cost at which they can be purchased through the program. Again, these costs can be adjusted to reflect additional factors.

The software offers two methods for estimating labor and overhead. One approach uses the ratio of your labor and overhead to material costs in the past and applies this ratio to future jobs. The second approach requires that you assign a number of labor hours to each cabinet and you assign a cost per hour to each category of labor.

The approach you decide to use depends on your shop and how consistent your product line is. If you build a more or less standard product line where the ratio of material, labor and overhead is about the same for all jobs, the standard cost system based on ratios will work well. If, on the other hand, you build a large variety of different products whose material and labor content varies widely, you should use the cost system based on hourly costs.

This area is vital to consistently making a profit and it is worth the time needed to analyze and understand how each approach works. Although there is some effort required to set up the initial data, once it is set up, developing a detailed cost estimate for a new Job is almost totally automatic. Because of its importance, we will cover this area in some detail.

There are three primary components to cost, *Material*, *Labor* and *Overhead*. If you add *Profit* to the sum of *Material*, *Labor* and *Overhead*, you get the *Selling Price*. If you take the *Selling Price* and subtract *Material*, *Labor* and *Overhead* you get *Profit*.

This is the basis for all accounting systems. Each of these areas, *Material*, *Labor* and *Overhead*, can be sub-divided and categorized to an almost incomprehensible degree, but every manufacturing company, from a small cabinet shop to the largest multi-national, strive, through their accounting systems, to determine *Material*, *Labor* and *Overhead*. As we work to understand our finances, keep this simple fact in mind. Now let's look at how we can handle each of these areas using eCabinet Systems.

The finance system within eCabinet Systems is not used to track actual cost, but instead is used to estimate the cost (*Material*, *Labor* and *Overhead*) of new jobs and help you determine a *Selling Price* that assures you of the *Profit* you want. This *Selling Price* then provides guidance for quoting and selling the job.

The more accurate your ability to estimate job cost, the more competitive you can be in the marketplace while assuring yourself of the profit you need to stay in business.

Your *Material Cost* includes wood based material, sheet stock, board stock and banding which you will process, other wood parts such as doors, drawer fronts and moldings, which you may or may not process, as well as components such as pulls, slides, hinges and other fittings which you purchase and use.

eCabinet Systems determines *Material Cost* by calculating how much material will be required to build the product, including the cost of cut-offs and scrap you need to throw away and then adding the cost of other components and material you need to purchase for the job.

The purchase cost of hardware and fittings are the cost at which you can purchase each item through the program, and as such are accurate. There are software features that allow you to adjust these numbers for the reality of your actual cost and as a result, *Material Cost* estimates generated by the software can be quite accurate.

Next comes *Labor* and here is where you must make a choice. Unlike *Material* which can be very accurate, estimating *Labor* is a less accurate science. Even building the same cabinet can take more labor one time than the next, so labor estimates are just that, estimates.

Since *Labor* is going to be an estimate, we need to determine how we want to generate this estimate. eCabinet Systems offers two different ways to estimate *Labor* for a job. You must choose one or the other.

The first method is based on *Material Cost*, which we have already established is accurate. For most shops that build a consistent product line, the ratio of *Labor Cost* to *Material Cost* is fairly constant. For example, for every dollar of *Material Cost* it may

require eighty cents in *Labor Cost*. This ratio of eighty cents *Labor* for every dollar of *Material* can be used to estimate *Labor Cost* for new jobs.

This approach will work well, if the ratio is fairly consistent across the product line. The ratio will be consistent if the product line is fairly consistent. This means that the basic material, construction methods and purchase items are pretty well the same for every job.

The ratio, however, is an average and averages can get you into trouble. If *Labor* is 120% of *Material* on one job and 40% on another, the average *Labor Cost* is 80%, but if you use 80% you will have problems. On the job with the lower *Labor Cost* you will price the job too high and possibly lose it. On the job with the high *Labor Cost* you will under price the job but will either have reduced profit or lose money.

As a general rule, if the *Material-Labor* ratio from job to job or from month to month stays within a 5% or so range, this approach will work and only requires that you establish the correct ratio. If not, you will need to use the second approach to estimating *Labor Cost* and that is to estimate the actual number of labor hours that will be required for each cabinet.

Using this second approach, you assign a cost per hour for one or more labor categories and then assign a specific number of labor hours to each cabinet in your library.

Some shops simply use *Shop Hours*. You can assign a cost per hour for *Shop Hours* and then assign a certain number of *Shop Hours* for each cabinet. If different jobs in your shop have different labor rates, you can use more than one category, assigning a different rate and a different number of hours for each category on each cabinet. In this way you can make these estimates quite accurate.

This information becomes part of the cabinet file. When a job is assembled, the system adds together the total labor hours associated with all the cabinets in the job and multiplies it by the cost per hour. The sum of the labor cost for each of the labor categories that you established is the estimated labor cost for the job.

The accuracy of this second approach depends on your ability to estimate the number of hours that will be required in each category and to accurately determine the cost per hour. It requires more effort to establish and maintain but can accurately estimate labor costs for shops that build a variety of different products that have different material-labor ratios.

The final category, *Overhead*, is not quite as straightforward as *Material* and *Labor*. *Material* and *Labor* are both, what accountants call, *Variable Costs*. This means they vary with the level of production. If you build twice as much, you will use twice as much *Material* and twice as much *Labor*.

*Overhead*, on the other hand is a *Fixed Cost*. Your cost for rent, power, insurance, bookkeeping, and all the other *Overhead* expenses is essentially the same each month

regardless of how much you produce. This makes it difficult to assign an *Overhead* expense to a particular job because *Overhead* isn't a cost actually associated with building the product, it is a cost associated with running your business. Nonetheless, we must find a way to account for *Overhead* expense in order to properly estimate the cost of a job.

As with *Labor*, we offer two ways to estimate *Overhead* cost for a job. Both methods estimate *Overhead* expense at a certain level of production. The easiest way is to use recent history and assume the immediate future will be like the recent past. This works provided you routinely recalculate the factors used in determining *Overhead*.

The first method we can use to estimate *Overhead* is by using historical ratios. When you select historic ratios to calculate *Labor*, this method is also used to calculate *Overhead*. Using this approach, we determine the ratio between *Overhead* expense and *Material Cost* and apply that ratio to the *Material Cost* of new jobs. If *Overhead* has been 25% of *Material Cost* for the last three months, we can assume it will be 25% of *Material Cost* for the next job.

The second method of estimating *Overhead* is using the concept of *Overhead Hours*. In this method, you divide the overhead for a month by the average number of hours you work each month to determine an *Overhead Cost/Hr*. Essentially this is how much you need to add to the cost for each hour of labor to pay for all your *Overhead*.

The system then multiplies this *Overhead Cost/Hr* by every hour assigned to the cabinet, regardless of the category, and calculates the *Overhead Cost* associated with this cabinet.

There is another category of expenses that accountants use called *General Administration and Selling Expense*. This is the cost for management, clerical help, advertising, and other expenses not directly used to produce a product. For our purposes, we will make these *General Administration and Selling Expenses* part of *Overhead* and handle all expenses that are not either *Material* or *Labor* as *Overhead Costs*.

### ***Important Considerations when Estimating Costs***

Understanding your costs is complex but important. If you don't understand your costs it is difficult or impossible to consistently make a profit. You could price your product high to insure a profit, but you will certainly miss out on sales. If you are aggressive in pricing and you don't truly know your costs, you will certainly accept business at a loss sometimes.

It is in this environment that we created the *Dynamic Cost/Price System* found in eCabinet Systems. Let us start with some definitions.

Throughout the program, *Cost* is how much you pay for something and *Price* is how much you sell something for.

The most basic item is *Material Cost*. This is how much you pay for something. Although this seems simple enough, this, along with the rest of the financial area, is not all that straightforward. If a cabinet pull costs you five dollars the cost is five dollars, right?

Not really. The pull actually cost you more than five dollars. Five dollars is how much you paid someone for the pull. It is also likely that you paid to have the pull, along with other items, shipped to your shop. A portion of that shipping cost represents cost for the pull. The pull, then, costs somewhat over five dollars.

This is still not the cost of the pull mounted on your finished product. After you received the pull, someone had to locate it, unwrap it, figure out where it is to be used and then mount the pull on the product. All of these actions require labor, and labor is something you have to pay for. The cost of doing these tasks also needs to be added to the cost of the pull. After all, if there were no pull on the door, none of these costs would occur so it is just right that they be considered part of the cost of the pull.

Are we finally done? It depends on how accurately you want to track your costs. There are other components to cost. Each year you might lose, damage or scrap some pulls. The cost of these items must be spread over the items you actually used to get a true cost. Then, the amount of time you keep the pull on the shelf affects its cost.

If you purchased the pull a year before you used it, you tied up five dollars in inventory for a year. If you are paying 9% to borrow money, the cost of the pulls actually increased by 9% or \$.45 during that year. Even if you don't borrow money, the five dollars could be put in an interest bearing account and you could have made some interest on it for the year. Therefore, the lost interest should be added to the cost of the pull.

Although these sound like pretty small numbers on a five-dollar purchase, if you apply them to everything you buy, the number becomes significant. The cost of the five-dollar pull alone could have easily increased a dollar to a dollar and a half. This is twenty to thirty-three percent. Even for small shops, undervaluing material cost by twenty to thirty-three percent is a serious problem.

When you try to determine the cost for material such as sheet stock or wood, the problem becomes even more involved. For items such as pulls, if you need one pull, you buy one pull and use everything you bought. With wood, however, you never quite use it all. There is always cut-offs and scrap material from any process. This is the material that you discard.

When you try to determine the cost for items made from these materials, you know the amount of material in the final product. You do not necessarily know how much wood it required to make those pieces. To help properly cost these items, the accountants have

come up with a term called yield. Yield is the percentage of the material that turns into the finished product. If three-fourths of a sheet of material is used in the final product and the other quarter is scrapped, the yield is 75%.

Yield is used as a kind of a backdoor way to determine the cost of the final product. For our example we will use some easy numbers. Assume a 4' by 8' sheet costs \$32. The sheet contains 32 square feet (4 X 8). Material costs \$1 per square foot (\$32 divided by 32 Sq Ft).

Let's use a 50% yield number. Half the 32 Square foot sheet or 16 square feet is used for the product and 16 square feet is scrap. The final product has 16 square ft of material in it.

If we take the final product and try to calculate cost, you would take 16 square feet times \$1 per square foot for a material cost of \$16. This, of course, is wrong.

It required a full sheet, which cost you \$32, to make the product, but we calculated a \$16 cost. To get an accurate cost we must not only calculate the cost of the material that ended up in the product but we must also add the cost of the material scrapped in making the product.

You could try to track your cost by counting the total sheets of material used for a job times the cost per sheet. We actually do just that when we calculate the cost of an entire job, however, it would be difficult to determine the cost of any particular item in the job using this method. Instead, when we deal with a single cabinet we will use the number of square feet in a finished product and then divide that by the yield, to determine the amount of material required to end up with the finished product.

Let's look at our example. If we take the calculated cost of \$16 and divide it by the yield (50% or .50) we end up with \$32 which is the actual cost of the material used in the product plus the material scrapped in making the product.

Although in our simple example it is easy to calculate the cost using the starting raw material, in real life, the calculations are much more complex and using the yield figure simplifies costing.

Most of you already know this, but it is important to understand all the underlying facts so that there is no confusion as to how we present our costing numbers. We will try to explain exactly how we handle these costs so that there is no confusion that might cost you money.

So far, we have only covered *Material Cost*. Luckily, this is the most complex of the terms we will deal with. *Selling Price* is how much you charge for the product you sell.

The next area is *Labor Cost*. As you might expect, this is the cost of labor needed to manufacture a product.

Next comes *Overhead*. This is all your expenses not directly tied to producing a product. It includes management salaries, travel, phone, advertising, insurance, rent, copy costs and a host of like items.

If you add the *Profit* you want on this job to the *Material*, *Labor* and *Overhead*, you get the *Selling Price*. This *Profit* number is actually more accurately, pre-tax profit. To get to the real bottom line we still have to subtract taxes.

This provides a very quick overview and some background to help determine the approach we want to use and how to determine the cost parameters we will need.

We will now go back and revisit the material area, focusing on the cost. Select the *Settings/Preferences* icon from the toolbar and then select *Define Stock Material*. This will bring up the material input sheet.

To obtain accurate cost estimates we must carefully specify the costs for various materials. It is these costs that form the basis of our cost estimates and therefore, it is quite important that they be correct when first entered and that they be adjusted whenever we learn of a change in material cost from our suppliers.

We have covered the basic input of material cost in the material area so now we will switch to the *Dynamic Markup* dialog where the core information is added.

From *Settings/Preferences* select *Define Costs*.

This dialog is used to specify basic information and choose the costing method you wish to use for cost estimate calculations. Once the information is entered in this area, the system automatically keeps track of *Material Cost* and calculates an estimate for *Labor* and *Overhead* costs for each Job. You can also determine the estimated cost of a cabinet or assembly in the *Cabinet/Assembly Editor*.

Cost estimate information is available from two sources, a Dynamic Cost Display along the bottom of the screen or a *Cost Sheet* report that can be generated from the *Cabinet/Assembly Editor* or from *Custom Layout* or *Batch Cabinets*. Note that a *Cost Sheet* for a Job includes costs for items added in both *Custom Layout* and *Batch Cabinets*.

## ***How to Calculate Material Cost***

There are three factors used to calculate *Material Cost*.

*Expected Yield %* is the average % of material that normally ends up in the finished product with the remainder being scrapped. This number is used to estimate how much material must be purchased for a Job (and thus the cost) by using the amount of material

in the finished product, which is a known amount. *Expected Yield* is used to estimate *Material Cost* until the Job is nested, at which point the exact amount of material required is known and used. The Dynamic Cost Display specifies if the costs presented are based on *Expected Yield* or *Actual Yield*.

*Percent Markup %* is a percent that the cost of material is increased to allow for miscellaneous costs directly associated with material such as shipping or scrap removal cost.

*Fix Markup \$* is an amount added to each material estimate to cover any fixed cost associated with each material.

Material Cost is the sum all *Material* required for the Job.

- Sheet stock, board stock and molding cost in the *Cabinet/Assembly Editor* is calculated by dividing the amount of stock required for the cabinet parts by the *Estimated Yield* to determine the cost of the stock needed before processing and then marking this up by the *% Markup* and adding the *Fixed Markup*.
- Sheet stock, board stock and molding cost in *Custom Layout* is calculated by dividing the amount of stock required for the cabinet parts by the *Estimated Yield* to determine the number of FULL SHEETS or FULL LENGTHS of material needed for the Job. The cost of these is then marked up by the *% Markup* and the *Fixed Markup* is added. If the Job has been nested, the actual number of full sheets or full lengths is used for this calculation.
- Purchased material cost is determined using the cost at which the item can be purchased through the eCabinet Systems program and then marking this up by the *% Markup* and adding the *Fixed Markup*.

#### Five Piece Door Cut List Detail

eCabinet Systems offers the user an ability to define necessary details about five piece doors required to give accurate part breakdown in the Cut List when the door/drawer front is designated as Build In House..

When in the Door/Drawer Front Designer, with a Five Piece Door/Drawer Front designated as Build In House loaded, click on the Details for Cut List button. This dialog will open where the necessary additional data can be provided. With this data provided the door/drawer front can be saved and anytime it is used the Cut List will show a breakdown with the necessary dimensions for all parts.

**Sizing Details for Cut List**

Coping Depth: 0 1/8"

Panel Inset: 0 1/8"

Perimeter Machining Allowance: 0 1/16"

Panel Board Stock: Generic 2 X 3/4

**Non-Thermwood Door Settings**

Rail Width: 4"

Stile Width: 4"

Arch Height: 1 1/4"

Stiles and Rails Board Stock: Generic 2 X 3/4

OK Cancel

## ***How to Calculate Labor and Overhead***

### **How to Calculate Labor and Overhead**

There are two different ways to estimate *Labor* and *Overhead* from which you can choose.

### **Calculating Labor and Overhead Using Historical Ratio Calculation**

This approach determines the historical ratio of *Labor* to *Material* and *Overhead* to *Material* and multiplies the *Material Cost* of a new Job by these ratios to estimate the *Labor* and *Overhead* cost for the Job.

Determine the *Ratio to Material %* for *Labor* by taking the direct *Labor* cost for a period of time (six months perhaps) and dividing it by the *Material* cost for the same period of time.

Determine the *Ratio to Material %* for *Overhead* by taking the *Overhead* cost for a period of time (six months perhaps) and dividing it by the *Material* cost for the same period of time.

*Fixed Markup \$* for both *Labor* and *Overhead* allows you to add a fixed *Labor* and *Overhead* cost to each cost calculation (either Job or cabinet depending on where the calculation is made).

## **Calculating Labor and Overhead Using Labor Based Calculations**

**Labor** - This approach specifies the *Cost/Hr* for various categories of *Labor*. Then an estimated number of *Labor* hours can be assigned to each cabinet for each category in the *Cabinet/Assembly Editor*. The system then multiplies the number of *Labor* hours assigned to a cabinet by the *Cost/Hr* to determine *Labor* cost for the cabinet.

**Overhead** – An *Overhead Cost/Hr* is specified here. *Overhead Cost/Hr* is calculated by taking the *Overhead* cost for a period of time (six months perhaps) and dividing it by the total number of *Labor* hours used during that same period. *Overhead* cost for a Job is calculated by taking the *Overhead Cost/Hr* and multiplying it by the total number of hours of all categories assigned to all the cabinets in a Job.

## **Calculating Profit Margin – Catalog Cabinets**

Profit for *Catalog Cabinets* is a straightforward calculation. *Material*, *Labor* and *Overhead Cost* of each cabinet is subtracted from the fixed selling price to get the profit.

## **Calculating Non-Catalog Cabinets - Profit Margin %**

*% Profit* - This is the percent of the FINAL SELLING PRICE that you want to be profit.

*Fixed Profit* – This is an additional amount you want added to the final selling price calculated using the *% Profit*.

## **Dynamic Cost Display**

This determines what information is displayed along the bottom of the screen.

Note that pressing and holding *Shift* and *\$* will display any data that is currently OFF as long as the keys are depressed.

## ***Alternate Source Door Cost***

This area is used to provide a cost basis for cabinet doors obtained from an alternate source. These doors are priced by adding a *Per-Door* cost to a *Per-Sq Foot* cost for each door.

## ***Displaying Cost/Price***

Cost/Price information is available in different areas of the software. A Dynamic Cost Display is available across the bottom of the screen. In addition, a report called a *Cost Sheet* can be generated in a separate window from either the *Cabinet/Assembly Editor* or *Custom Layout*. This report is somewhat different depending on whether it originates in the *Cabinet/Assembly Editor* or from *Custom Layout*.

The Dynamic Cost Display across the bottom of the screen is controlled from the *Edit – Preferences* area. Select what you want to display from the list of displays at the bottom of the screen.

- *Material Cost* is how much you pay for the materials and components used in building the cabinets that are part of the job. *Material Cost* is determined by the amount at which you can purchase the item through the program or it is the cost that you input for materials, adjusted for any additional costs and the yield for that material.
- *Labor Cost* is the estimated cost of labor for this Job.
- *Overhead Cost* is estimated cost of labor for this Job.
- *Profit* is the total amount of profit for this Job calculated using the *Profit Margin %* and *Fixed Profit* you specified.
- *Selling Price* is the amount you sell something for. For custom cabinets, the *Selling Price* is a calculated number. It is determined by “marking up” the *Total Cost* to generate the *Profit Margin %* and *Fixed Profit* you want for the job. The *Selling Price* for *Catalog Cabinets* is the price you input for each cabinet.

Displays for each area can be turned ON and OFF in the *Settings/Preferences* area. These displays are at the bottom of the screen and show a running total for the entire job. As you change things, the various displays reflect the financial impact of the changes.

If you have any of the Dynamic Cost Displays turned off, pressing *Shift* and *\$* will display them as long as the keys are held down.

A display to the right indicates whether you are using an *Estimated Yield* based on the expected yield you entered as part of the material parameters or *Actual Yield* based on the yield that results when the job is nested.

To set up the *Dynamic Cost Tracking* display, select ON for each item you want displayed and OFF for the items you do not want displayed. If *Material*, *Labor* and *Overhead* are all ON, *Total Cost* will also display. If any of them are OFF, *Total Cost* will not display.

The *Dynamic Cost* displays operate continuously, except in the *Detail Room*. The rather involved continuous cost/price calculations slow program execution so we suppress these calculations in the *Detail Room* area. To view the *Dynamic Cost* displays in *Detail Room*, right click and select *Display Cost/Price*. The *Dynamic Cost* displays then shows the current costs and prices. As soon as a change is made to the room, these displays are removed.

## Using the Cabinet/Assembly Editor

### *Using the Cabinet/Assembly Editor*

This is the place where you develop and save your own cabinet and furniture designs. Some of the front end of this chapter is a repeat of information presented in the software overview. Please read through it again here. It is important that you understand these basics to make the software easy to both understand and use.

To create a library of your own designs, you start with a standard cabinet from a seed directory called “Standard Cabinets” and modify parameters until you fashion a cabinet designed the way you want. This new cabinet is saved under a new name in a new directory.

This cabinet can then be loaded, further modified and saved under yet another name.

This approach makes development of entire libraries easy and yet provides almost total flexibility.

The key ingredient to the eCabinet Systems approach, is the ability to display highly detailed, accurate graphic images of the cabinet. These images show exactly what the cabinet will look like using the current parameters. Changing a parameter causes the image to change, reflecting that change.

This image can be moved, rotated, exploded and zoomed. Components can be hidden, made transparent or turned into wireframe. In short, you can twist, turn, zoom and examine in minute detail the actual effect on the cabinet of any parameter changes.

This approach makes the adjustment process both easy and clear.

To develop a library, start with a standard cabinet. Change this cabinet to include all the parameters you want to be shared by every cabinet in your new library. Save this in a new directory as a “seed” cabinet.

Now, load this seed cabinet, resize and modify it to the first cabinet you want in your library. Save it. Load the seed cabinet again, create and save your next cabinet. In a short time you have an entire library of cabinets that all share the same characteristics as your seed cabinet.

Should you need to change any of these for a specific application, it is easy because the parameters reside with the cabinet, not the software. So, exactly how do we change the cabinet parameters?

We can separate changes to the cabinet into three categories, size, configuration and parameters.

Size is essentially height width and depth of the cabinet. This is changed on the *Main* page of the *Cabinet/Assembly Editor* but can also be changed whenever the cabinet is used in a job.

Configuration includes shelves, partitions, face frames, moldings, doors, drawer boxes, etc. The configuration of a cabinet is developed through a series of *Editors* that are reached from the *Main* page.

The *Editors* use the concept of *Default* components or settings. This means that many details such as door design, drawer front and drawer box design, pulls and moldings have a “Default” selection so that they do not need to be selected each time they are used. When one of these components is added to a cabinet, the current “Default Selection” is automatically used; therefore using a specific design is a two step process. First, the design is located and designated as the “Default” generally using a *Set Default* button. Then, Then the item is added which automatically uses the “Default” selection.

Parameters are the little bitty details concerning everything about the cabinet. Material, joinery, fits, insets, and about everything else. These parameters are adjusted in an area called *Construction Settings* that is also reached from the *Main* page or, they can generally be reached from any of the configuration *Editors*.

There are actually two kinds of parameters in *Construction Settings*, which can cause some confusion. Some parameters, a *back inset* for example, affect the cabinet as soon as they are changed. Other parameters define how items, a shelf for example, are added to the cabinet. Changing this type of parameter doesn't change existing shelves, it only affects shelves that are added after the change. Of course, to make it even more confusing, if you highlight a shelf and then make a parameter change it changes the shelf that was highlighted.

You can tell what type of parameters you are adjusting by the title on the tab. If the word “Add” is in the title (eg. Add Shelf Settings), the changes will only affect newly added components. If the word “Add” is not in the title (Toe Kick, Back, Left End, etc) then any changes you make will immediately change the cabinet.

It's actually pretty simple. Change size on the *Main* page or when you use the cabinet, change configuration using *Editors* and change parameters in *Construction Settings*.

Regardless of how many configurations and parameters the software allows for, cabinetmakers will always want to do something more. To address this, a *Part Editor* is available. Using the *Part Editor*, any part of the cabinet can be cut, pocketed, profiled or machined. This lets you create almost anything you can imagine. The amazing thing is that all of these creations can be actually machined on a Thermwood CNC router from the file created by the *Part Editor*. You can cut and profile individual cabinet parts pretty much any way you want.

If you want to put an edge profile on a part, you will need to develop a tool with the correct profile. This tool is developed in an area called a *Shape Manager*. Tools developed in the *Shape Manager* are used in the *Part Editor* to cut a profile on a part.

An interesting note about this feature is that once a profile is placed on a part in the *Part Editor*, that profile can be machined on a Thermwood CNC router even if a custom profile tool is not available. The Thermwood control can create a modeling program using a ball nose and corner bit to machine the edge using modeling techniques.

When you modify a part in the *Part Editor*, you should also define how the changes you made will react should the part size change. This is done through a *Configuration Manager* whose purpose is to define how modified parts in the *Part Editor* react to cabinet size changes.

So far it has been pretty simple but now we are going to add a valuable feature that can make it a bit more confusing if you don't understand it. It has to do with the word "Assembly" in *Cabinet/Assembly Editor*.

A lot of complex cabinets and furniture cannot be defined with a single set of parameters. The approach eCabinet Systems uses to create these more complex pieces is to allow multiple cabinets to be loaded into the *Cabinet/Assembly Editor* at the same time and saved together as an "Assembly". This approach is very powerful, but can be confusing. Let's look at an example.

Suppose we need an upper island cabinet with a face frame and doors on both the front and back. We need to remove the back and put a face frame and doors on it.

In designing software to allow for this, you could create parameters for a face frame and doors on the back. But, there are thousands of these types of variations and you simply can't make parameters for everything or the software would really get confusing. Instead, eCabinet Systems allows you to combine elements from two or more cabinets into an Assembly.

In this case, we take our first face frame cabinet and remove the back. Then we take a second copy of the cabinet (we can copy and paste it right there) and remove everything except the face frame and doors.

At this point the software sees two cabinets, one without a back and one without everything except the face frame and doors. Move the face frame and doors from the second cabinet to the back of the first cabinet and we have the assembly we want. It looks like a single cabinet with a face frame and doors on both ends but we know that, as far as the software is concerned, it is actually two cabinets, each with parts removed.

We can address and change the parameters of either cabinet by highlighting it and accessing *Construction Settings*.

In addition, other items can be loaded and included in either a cabinet or in the assembly.

Certain items that can be purchased through the program also have 3D images that can be loaded and added to either the cabinet or the assembly. This can get confusing because some of these items can be added to the cabinet in two different ways. For example, you can load a door pull as a Vendor Item and then locate it on a door. You can also load the same pull in the *Door/Drawer Editor* and locate it on the door. The difference in these two approaches is that when a pull is loaded in the *Door/Drawer Editor*, the software knows it is a door pull. When the cabinet size is changed, the location is automatically adjusted for the new size.

When the same door pull is loaded as a vendor item, the software does not know what it is. When the cabinet size changes, the location of the item does not change and is probably wrong at that time.

Other vendor items, a lazy Susan for example, does not have this conflict. The software doesn't know what a lazy Susan is so adding it as a Vendor Item is the only way to display it. If you change the size of the cabinet, you will probably need to adjust the location.

A lot of items available through the program are in this category.

Another type of item that can be added to a cabinet or assembly is called a *Display Object*. These are item that you have a display file for but are not available from a vendor. These can be added to the cabinet although many times these types of items are added when a *Custom Layout* is developed. In general, if the item should appear each time the cabinet is used, a brass mounting foot for example, it should be part of the cabinet. If the item is sometimes, but not always, used with the cabinet it should be added in *Custom Layout*.

You can change the size of a *Display Object* by first highlighting it. Then you can either select *Edit – Scale Selection* from the top menu or right click and select *Scale Object*. This opens a scale dialog where you can adjust the size of the object.

This is a good time to discuss associations, cabinets and assemblies. This is another area that can be confusing if you don't understand the underlying principles.

A “cabinet” is the smallest entity that can be saved.

A cabinet includes parts of the cabinet itself, but also includes any other items that are “associated” with it. An item that is associated with the cabinet is part of the cabinet. These associated items include Vendor Items, Display Objects, moldings, doors and drawers that are added directly rather than through the *Editors*, display cubes, panels and boards.

There are two ways to associate an item with a cabinet. First, if you highlight the cabinet and then load the item, the item is associated and is part of the highlighted cabinet. There is also a selection from the *Right Click Menu* that you use to associate and disassociate.

When a cabinet is saved as a cabinet, all items associated with it are also saved as part of the cabinet.

When you save an “assembly”, everything in the workspace is saved in their relative position to each other as an assembly file. This includes all the cabinets and all other items. To make it even more confusing, an assembly does not need to include a cabinet. You can load one or two display objects and save them as an assembly.

Moldings, doors and drawers and drawer boxes can be directly loaded as individual items rather than installing them through their Editors. This is like the “door pull” example we just covered. If the moldings, doors, drawer fronts and boxes are added through the appropriate Editor, the software knows what they are and makes appropriate adjustments when the cabinet size changes. If they are loaded directly, the software does not know what they are and makes no adjustments. Whatever is loaded remains the same and is unchanged even if the associated cabinet changes.

There are times when the ability to add these items without using the Editors is needed, which is why the capability is included in the software, however, normally these items are added in their individual Editors.

The final items that can be loaded are *Display Cubes*, *Display Panels* and *Display Boards*.

A *Display Cube* is strictly for display, but can be a powerful display tool. It is basically a cube, you determine the size, on which an image is placed. It has a wide variety of uses, although it tends to be used more in developing custom layouts than in the *Cabinet/Assembly Editor*. As an example, if you built a picture frame and wanted to put a picture in it, you could create a thin *Display Cube* and stretch a picture image over it and then locate the cube inside the frame. If you built a speaker box and need a cloth covering for the front, you could make the covering as a *Display Cube*. In *Custom Layout* a *Display Cube* can be used to simulate almost any appliance.

*Display Cubes* are even more useful because they can be taken to the *Part Editor* and their shape modified. In the end, however, they are simply tools used to display. *Display Panels* and *Display Boards* have one additional feature, they can actually be manufactured.

A *Display Panel* is a rectangular panel made from any sheet material in your library. You simply specify the size and material and then locate it as you want. Like the *Display Cube*, a *Display Panel* can be taken to the *Part Editor* and modified. The advantage the *Display Panel* has is that it is an actual part that shows up on the *Cut List*, nest diagrams, part drawings and CNC programs. A *Display Panel* can actually be manufactured.

A *Display Board* works the same way but using board stock rather than sheet stock.

Now that we have examined the various items that can be loaded into the workspace, we should probably load something.

In almost every area of the software clicking the right mouse button brings up a menu. Items are loaded by right clicking and selecting *Load Item*. You can also click the load icon on the toolbar.

You can configure the workspace to suit your personal taste. Grids, axis lines and colors can be turned on and off. These are reached through a *Grid Settings* icon in the toolbar. Within the workspace is an *Insert Target*. This ball with axis lines protruding indicates where the next item will be loaded.

The *Insert Target* can be highlighted and moved so that one item is not loaded over or inside another. You highlight the *Insert Target* by double clicking on it, or if it is imbedded in an object it can be highlighted by pressing Ctrl + T.

The *Insert Target* is moved by holding the *Ctrl* key and using the Right Mouse Button.

Normally you don't try to precisely locate an item using the *Insert Target*. Instead, it is used to keep items apart and then *Align* tools are used to quickly position items with respect to each other.

As you begin to load a cabinet you will notice that cabinets are divided into "types". Base cabinets, upper cabinets, islands, tall, base corner, upper corner and detached toe are the cabinet types. With the exception of corner cabinets, the difference in cabinet type is not in the cabinets but in how the cabinet is handled when placed in a room in *Custom Layout*. With a few parameter changes, an upper cabinet can be turned into an exact copy of a base cabinet except it will be placed higher off the floor when added to a room. You could move it down in which case it would work just fine except, when all base cabinets are selected in some editing functions, the upper turned base will not be selected because it is not a "base" TYPE. A base cabinet can be turned into a detached toe. In fact, if you need a face frame, a base cabinet with a face frame can be turned into the face frame only by removing all the cabinet parts except for the face frame. The point of all this is that for all these different cabinets, you only have one set of settings and parameters to learn. They work for everything.

That being said, you should realize that you cannot change a cabinet's type. Once it is an upper, it is always an upper even if it looks exactly like a base or toe kick. This means that it will initially be positioned a specified distance above the floor when placed in a room and will be selected whenever *All Upper Cabinets* are accessed

The starting cabinets in eCabinet Systems are called "Standard" cabinets and are located in the "Standard Cabinets" directory. There are separate cabinets for frame versus

frameless to make it more convenient but realize you can change frame cabinets to frameless and back at will. The frame cabinets all have face frames, are made from material called “generic” and have slab doors and drawer fronts. Their actual configuration is not all that important because they will not work for any shop the way they are but simply offer a starting point. They also allow you to begin using cabinets in *Custom Layout* without having to develop your own library first.

The frameless standard cabinets are a stripped down minimum box without doors or shelves to which you add the components you will need. The frameless standard cabinets simply save you the effort of removing the doors, drawer, face frame and shelf from the frame cabinets.

The frame cabinets however, allow you to begin working with and learning other aspects of the software without having to develop a library of cabinets first.

The *Standard Cabinets* directory is used solely to hold the *Standard* cabinets. You cannot save cabinets in the *Standard Cabinets* directory. You must save them to a newly created directory. Also, it is recommended that you change the file names when you save them.

With a little forward planning, this approach can make development of entire libraries of cabinets easy. You need to start by analyzing the library of cabinets you need and considering shared features of the cabinets.

The first step is determining which characteristics are shared by the entire library of cabinets and modifying *Standard* cabinets to these characteristics. For example, all your cabinets may use  $\frac{3}{4}$  inch sides of a specific material and a  $\frac{1}{4}$  inch back. The back may full dado into the sides and they may all use blind dado construction.

The cabinets may use a specific door and drawer front design and specific hardware. You can set the door, drawer and hardware as *Defaults* although you do not want to put them on the cabinets at this time.

To begin, you may want to modify a base cabinet and an upper to these characteristics and save them as “seed” cabinets for this library. Now, You can use these “seed” cabinets to develop the individual cabinet designs needed for your library, knowing that you do not need to address all these settings and defaults for each individual cabinet.

This approach can be taken several levels deep. For example, after developing the initial “seed” cabinets, you may decide you need a subset of these for another application. For example, you may want some of these cabinets with a detached base. In this case, you can take the normal “seed” cabinet, modify it to a detached base cabinet and save it as a “detached base seed” cabinet. Now any cabinets you want to make with a detached base should start with the “detached base seed” cabinet.

The takes a little analyzing and planning but pays off in much faster and more consistent designs.

Let's load a cabinet so we can examine some additional features. Right Click, select *Load Item* then click on *Cabinets*. Click on the *Standard Cabinets* directory. Note, you must click on the name itself, NOT the checkbox. This can be a bit confusing but the checkboxes are used to select items, or in this case directories that are then deleted by pressing the button at the bottom of the list.

Now click on *Std Base Frameless* and press OK. Again the checkbox is for deleting the item not selecting it.

You are now viewing the *Main* working screen of the *Cabinet/Assembly Editor* with a cabinet loaded. This screen is used for basic assembly tasks and for viewing the current state of the cabinet design.

Let's look at some of the characteristics of this screen.

You are basically looking at a three dimensional workspace defined by three axes, X,Y and Z. The entire workspace is rotated by holding the Shift key and using the LEFT mouse button, it is panned using the *Shift* key and RIGHT mouse button and zoomed using *Shift* and BOTH mouse buttons.

These motions are important so you should take some time and work with them until you are very familiar with their operation. Before long these motions will become second nature.

Display of the workspace can be customized using the *Grid Settings* icon. This opens the dialog shown.

A background grid can be displayed on each axis plane and the appearance of the grid is determined by the *Grid Type* setting.

The spacing of the grid elements can be set and, since we are working in an unlimited three-dimensional workspace, we also need to define the size of the grid. The number shown under *Grid Size* indicates the number of grid spaces on each side of each axis. For example if you set the *Grid Spacing* at 10" and set *Grid Size* at 10, you will have a grid that is 100 inches on each side of the axis or a grid that is 200 inches across.

At different times it may be useful to have the grid display on different planes. The planes on which a background grid displays is controlled in the *Grid Planes* area.

You can also decide which axes to display and the color to display it in.

A three dimensional *Axis Designator* icon is available at the lower left of the screen. This icon rotates with the workspace and is quite useful in determining which axis is which, when working with rotated assemblies. This *Axis Designator* color codes each axis with X being red, Y blue and Z yellow. It is recommended that you set the axis displays to these same colors to make the workspace more consistent and easier to understand.

There is also an *Insert Target* which we have already discussed. It initially appears at the origin where the axes intersect. This target determines the location where an item, such as a cabinet, is inserted into the workspace when it is loaded. This *Insert Target* can be moved by first highlighting it by double clicking on it and then while holding the *Ctrl* key, using the right mouse button. If it is hidden inside a cabinet, you can also highlight it by pressing *Ctrl* and *T*.

In addition to moving the entire workspace, you can also move and rotate items within the workspace. An item (cabinet, display part, etc) is moved by highlighting it and then holding the *Ctrl* key while using the Right Mouse Button.

This may be a good time to introduce another feature of the workspace, the *C-Plane*. When you first enter the *Cabinet/Assembly Editor*, you are looking directly at the *XY Plane* with the X Axis defining left and right movement and the Y Axis defining up and down motion. The *C-Plane* is also set to the XY Plane called *C-Plane Front*. This means left and right movement of the mouse moves items along the X Axis and up and down movement of the mouse moves items along the Y Axis, or mouse movements correspond to a front view.

Since you can rotate the entire workspace, should you rotate the workspace so that you are viewing the left side, left to right movement of the mouse still moves along the X Axis but now that means front to back movement on the display.

To get left and right mouse movement to move items left and right in this new orientation, the *C-Plane* needs to be changed to *C-Plane Left*. This is even more important at random rotation angles.

Note that you can change viewing orientation using the arrow keys, left, right, top and bottom. The *Home* key is the front view and the *End* key is the back view. When you use these keys to change viewing orientation, the *C-Plane* also changes to the corresponding orientation automatically. When working at intermediate angles, you can change the *C-Plane* manually.

As a note, there is a rotate dialog that is used to rotate items within the workspace. There is more information on moving and aligning items in the section titled “Moving and Aligning Items in the Workspace”.

From this position we can start to modify the cabinet. As stated earlier, these modifications are three types, size, configuration and parameters. We will start by

changing size although, most of the time size changes are done as part of adding the cabinet to a job.

To change size, input a new size in either *Width*, *Height* or *Depth* and press *Enter*. The cabinet will change to reflect the new size. Should you ever try to create a size that isn't workable, the system will catch the error, alert you and restore the previous size.

## ***Loading an Item into the Workspace***

Select the *Load Item* icon on the top toolbar or right click and select *Load Item*.

Select the category of item you want to load.

- **Cabinets** - These are individual cabinets to which a set of cabinet parameters applies
- **Assemblies** – This is a grouping of two or more cabinets or other items saved as a single entity
- **Vendor Items** – These are items available for purchase through the program for which three-dimensional display images are available
- **Display Objects** – These are three-dimensional images whose primary function is to enhance overall appearance. Note that the scale of these objects can be changed.
- **Moldings** – These are lengths of molding that are added to the workspace as Display Items. Moldings can also be added to a cabinet in the *Molding Editor*. Moldings added in the *Molding Editor* automatically resize when the cabinet resizes but are restricted to horizontal orientation. Moldings added here, as a Display Item can be placed in any orientation but do not resize automatically.
- **Display Cubes** – These are cubes of any size on which an image can be stretched or tiled. They are used for display purposes to enhance overall appearance and are highly flexible. Display Cubes can be modified in the Part Editor.
- **Display Panels** – These are rectangular panels made from a specific sheet material that can be loaded into the workspace and positioned in any

- orientation. Display Panels can be modified in the Part Editor and appear on the Cut List, Nest Diagram and CNC output.
- **Display Boards** – This is a length of board stock that can be loaded into the workspace and positioned in any orientation. Display Boards can be modified in the Part Editor and appear on the Cut List.
  - **Doors/Drawers** – This is a door front or drawer front of a specific size that can be loaded into the workspace and positioned in any orientation. Once loaded, it does not change size as cabinets within the workspace change size. To add a door or drawer front that resizes with a cabinet, it should be added using the *Door/Drawer Editor*.
  - **Drawer Boxes** – This is a drawer box of a specific size that can be loaded into the workspace and positioned in any orientation. Once loaded, it does not change size as cabinets within the workspace change size. To add a drawer box that resizes with a cabinet, it should be added with a drawer front using the *Door/Drawer Editor* or added without a drawer front using the *Drawer Box Editor*.

Note that all items except cabinets and assemblies can be associated with an individual cabinet. This means it is part of the cabinet and saves with the cabinet but does not resize with the cabinet. There are two ways to associate an item with a cabinet. First, if a cabinet is highlighted when an item is loaded, it is automatically associated to that cabinet. You can also associate an item with a cabinet by highlighting the item (single click on it) and highlighting the cabinet (double click on it), then right click and select *Associations – Associate to Cabinet*. You can disassociate an item using essentially the same process.

## Cabinet Joinery

There are several types of joints that can be specified between cabinet parts and there are several places where these joints can be changed. Note that every joint between every part can be independently set, providing great flexibility but adding some complexity.

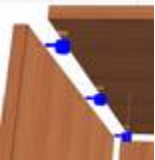

The types of joints available are:

- **Butt** – In this joint the edge of one panel butts against the surface of another. This joint will require some type of mechanical fastener such as screws or nails.

- **Blind Dado** – This is a joint specifically designed for machining by a CNC router. A tenon, shorter than the length of a panel edge is machined into the panel edge. A corresponding mortise is machined into the mating panel surface. The resulting joint is both strong and easy to assemble.

-  **Full Dado** – This joint cuts a dado into the surface of one panel and lengthens the corresponding panel to fit into the dado which extends across the entire edge.
-  **KD/RTA** – This joint supports KD (knock down) or RTA (ready to assemble) hardware fasteners. The hole pattern for these fasteners can be developed in the *Hardware Hole Editor* however, most KD/RTA fasteners available through the program already have the correct hole pattern developed and associated.
- **Dowell** – Dowell construction is essentially a butt joint with holes drilled into both panels which are then assembled by placing dowels in the holes. In the software, dowel construction is handled the same as butt joints.

There are several ways to change joint construction. First, you can change the joint type on every part of the cabinet in *Construction Settings*. From the *Main* page of the *Cabinet/Assembly Editor*, right click and select *Construction Settings*. Then select the *Global Settings* tab and change the *Construction* to the joint you want and press *OK*.

Also, each of the areas within *Construction Settings* has a *Construction* box where you can change joinery for that particular part.

Another way to change construction joint on a part is to right click on the part on the *Main* page of the *Cabinet/Assembly Editor* and then select *Construction* and the particular joint you want to change. Then, click on the joint type you want and it changes. This is rather quick and simple and sounds more complex than it really is.

Not only can you select the joint you want, you can also adjust the actual physical characteristics of the joint. The software comes with these parameters set to a workable average but all the parameters can be adjusted as needed, although this area can get a bit involved.

With the exception of certain dado settings, the joint construction parameters must be changed for each individual component of a cabinet, one at a time. The exceptions to this are the *Depth*, *Depth Clearance* and *Fit Clearance* of all dados and the *Thickness* of a blind dado. These parameters are the most common to change and they can be changed for every joint in the cabinet in the *Global Settings* area.

For each part of the cabinet there is an area in *Construction Settings* where its parameters can be adjusted. At the bottom of each area is a button that accesses the “*Construction Parameters*”.

We are not going to address each construction parameter in this manual, however, each has a pop-up guide box that explains its function and purpose. Be sure to review these as well as the Area Overview, which is different for each area and is accessed by pressing the ? icon.

## ***Modifying Cabinet Parts***

For the purpose of this section we will consider cabinet parts to be those parts that do not have their own *Editor*. These include top, deck, sides, back and toe kick plate. The outside frame of the face frame also behaves like a cabinet part but we cover that in detail in the face frame discussion so we will not deal with it here.

Cabinet parts, as defined above, are controlled by *Construction Settings*. Parameters that define these parts are stored in the *Construction Settings* area and you modify those parts by modifying the parameters.

Some of the things you can modify are the material they are made from, their size with respect to the cabinet, the joinery and overlap between parts, in some cases their position, such as inseting a back. You can also indicate whether the part exists at all on this cabinet.

Probably the best way to learn this is to load the *Std Base Frameless* from the *Standard Cabinets* directory and then go to *Construction Settings*, make changes and see what happens.

There are a couple of ways to get to *Construction Settings* and a neat shortcut that can save time once you learn it.

You can launch *Construction Settings* using the icon in the toolbar or you can right click and select *Construction Settings*. Once you get to *Construction Settings* you click on the tab for the part you want to work with. The neat shortcut is that if you right click on a cabinet part and then select *Construction Settings* it will automatically take you to the area for the part that you clicked on. You don't have to click on the tab. OK it doesn't save a lot of time but every little bit helps.

## ***Working with the Top***

The top is a little different than other components because you have a choice of several types of top. You can, of course, have none or a full top that covers the whole cabinet, but you can also have a stretcher top or a web frame top.

These are two designs that are common in building cabinet. The stretcher top has one or two stretchers that extend left to right. The web top has one or two webs that extend front to back.

The first thing you need to do is check the material. You can change the material for each component independently but, if you want to change the entire cabinet you can change all material in the cabinet at one time by clicking on *Global Settings* and changing it there. Even if one part is a different material, say the back is thinner, you can change the whole cabinet in *Global Settings* and then you only have to adjust material for that one part.

There is also a handy button that takes you to the *Define Materials* area of *Settings Preferences* where you can add new material if you need to.

Let's start with a full top. The first thing you can do is inset the top. This means you can move it down into the cabinet. You can also specify a negative inset and move it above the cabinet but I am not exactly sure why you would do this. This parameter is called *Top Inset*.

We are going to work with a lot of insets and there is one characteristic you need to understand so we will cover it once here and then you need to remember it as we work with other insets. Insets change the part from the size or position it would normally be on this cabinet. If you inset the top two inches, it is located two inches below the top of the cabinet. If you now change the height of the cabinet the top is still two inches below the top of the cabinet. A two inch inset means make it two inches below where it is normally located. This same thing applies to insets on all cabinet parts.

Cabinet parts automatically change when the cabinet size is changed. Insets are then applied to the new size for every part.

In addition to insetting or making the part smaller, you can also apply a negative inset and make the part bigger. When doing this, however, you may actually mesh one part into another. The system does not prevent this because there are valid reasons why you might want to do it. For example, if you wanted to join two panels with a miter, each panel would need to be full length and they would mesh where they meet. When it comes to negative insets, you are in charge of making sure they will work in your application.

One other feature that might go unnoticed is that when you click inside an *Inset* box, the diagram changes to show you the effect of a positive and negative inset for that parameter. This can save a lot of trial and error when you first start using the software.

The other thing we need to understand is placement. You will see some terms here that are not a standard part of cabinet vocabulary. They are *Side Flush*, *Top Flush*, *Back Flush*, etc. These describe how one part overlaps another and can get a bit confusing.

Basically, the part that is called *Flush* overlaps the other part. If you are working with the top and the side, if you specify *Top Flush*, the top will overlap the side. If you specify *Side Flush*, the side will overlap the edge of the top.

For the top you have three choices, *Side Flush*, *Top Flush* or *Mixed Flush*. *Top Flush* means the top extends over the edge of both sides and the back. *Side Flush* is a bit misleading because it means that the sides extend over the top but it also means that the back extends over the top.

*Mixed Flush* means you can specify each edge independently and they can be different from each other. When you check *Mixed Flush*, the area below lights up where you can select the *Left Side*, *Right Side* and *Back*. As with the other insets, when you select an overlap, the little diagram below shows you what you selected.

Something you might note is that when you add a *Top Inset* the placement changes to *Side Flush*. If you then specify *Top Flush*, the ends and back will be shortened so that the now lowered top can overlap them. This same thing occurs for each part independently. If you inset the top and then select *Mixed Flush* and set the back as *Top Flush*, the back is shortened so that the top can overlap it. This gets a little tricky so work with it until you understand what is going on.

The *Grain Direction* control lets you specify the angle at which the wood grain runs on this part. You can control grain angle on every part but remember that when the system nests these parts they will be rotated in the nest so the grain runs the way you specified and yield could go down pretty fast.

You can also control the individual joints that the top makes with other components. Obviously, you can specify joints with insets and overlaps that just won't work in combination with each other. The system will watch this provided you press the *OK* button each time you change joints. The system will let you go to several different parts and change joints on each before you press *OK*. When you press *OK* the system tries to build a cabinet obeying all the parameters. If a parameter on one part says one thing and a parameter on another specifies something else for that same joint, the system will pick one and it may not be what you want. It is a good practice to press *OK* each time you finish with a part and then reenter *Construction Settings* to work on the next part.

That's about it for the full top. Next is the stretcher top. When you check *Stretcher Top* you get a couple of extra dimension boxes to define the front to back width of each stretcher. If you don't want one or the other, set its width to zero.

At this point, the *Front Inset* controls how far the front edge of the front stretcher is from the front of the cabinet. The *Back Inset* controls how far the back edge of the back stretcher is from the back of the cabinet. With these control you can put pretty much any width stretcher anyplace across the top.

The web area is pretty much the same as the stretcher, except the pieces go from front to back rather than side to side.

That is the top. When you first start using the software you should make a lot of changes and then go back and see what they did. A little bit of time spent playing with the settings will make this all clear rather quickly.

## ***Working with the Back***

As installed in the standard cabinets, the back is the same material as the sides, top and deck and runs from the top to the floor. Most cabinet shops will want to change this.

The back is changed like other cabinet parts in *Construction Settings*.

First, there is an argument for keeping the back as the same material as the rest of the cabinet, especially if you are cutting it on a CNC. With blind dado construction and a thick back you get a really strong cabinet box. The slightly higher cost of this material is partially offset by the efficiency of having to process only one material. In the end these are decisions that each shop must make. We will show you different ways of handling different materials.

Other than selecting a back material, changes to the back consist of defining insets and construction joints.

Insets and placement (overlap) work the same as other cabinet parts. See the section on “Working with the Top” for a complete description of these functions.

From this area you can control overlap on the left and right sides but not the deck. Many cabinetmakers like to stop the back at the deck. The easiest way to do this is to go to the *Deck* area where you can set the overlap between the deck and the back. Set this to *Deck Flush* and the back will end against the deck.

For those that use a thinner back material, there are two ways it is commonly constructed. The simplest is to change the joint to *Full Dado* with a zero *Back Inset*. The back can then be placed in this rabbit and pin nailed in place.

A more structurally sound approach is to change joint construction to *Full Dado* and inset the back. If you also set the top to *Back Flush*, The back can be slid into the slot from the top and then pin nailed to the edge of the top.

Both approaches allow the cabinet to be assembled without the back and then the back added later. This is valuable if you plan to spray finish the interior because by spraying

before the back is applied, you will eliminate blow back and the entire process becomes much easier. The back can be finished separately and then assembled after it is dry.

### ***Working with Cabinet Ends***

There are not a lot of adjustments available for cabinet ends. You can change material and inset the panel or extend it by using a negative inset. For details of how insets work see the section “Working with the Top”.

Construction joinery is set on the components that connect with the ends.

The notch at the bottom front for a toe kick is set in the *Toe Kick* area.

### ***Working with the Deck***

In the deck area you can select a material for the deck as well as set placement (overlap) with the cabinet sides and back.

In setting the overlap to *Deck Flush* with the sides, there are some restrictions such as not having a toe kick. There are ways to achieve this with the toe kick should you actually need it by insetting the cabinet end at the bottom and putting a negative inset on the deck.

Insets and overlaps work the same as other areas. You might want to refer to the section “Working with the Top” for a detail explanation of these parameters.

### ***Working with the Toe Kick***

There are basically two types of cabinets, those with the toe kick cut into each cabinet and those that use a detached toe kick base on which one or more cabinet are mounted. The software supports both.

In the Toe Kick area there are actually three choices. You will see two check boxes. One says *Has Toe* the other *Detached Toe*. You will also find that you can uncheck both.

The *Has Toe* checkbox determines if the front toe plate exists. If it is checked, a toe kick panel is placed between the cabinet ends and under the deck. The *Height* and *Inset* determine where the toe kick panel is located and also control the toe kick notches in the cabinet ends.

The *Height* of the toe kick also determines the location of the cabinet deck. As you change the *Height*, the deck moves up and down to accommodate the height of the toe kick.

If you uncheck *Has Toe* but leave a distance in *Height* and *Inset*, the cabinet ends will be notched for the toe kick but no toe kick panel will be installed. Sometimes this is used when you want a common toe kick panel across a series of cabinets.

When you specify *Detached Toe* you must also input *Height*. This is the height of the detached toe base you plan to use.

When you do this, the cabinet box itself is shortened so that when it is sitting on the detached toe base, the top of the cabinet will be the *Height* above the floor that is set as the overall cabinet *Height* in the dimension box at the upper left. If you set the cabinet height as 34.5 inch and set the detached toe kick height at 5 inches then the cabinet box itself will be 29.5 inches high even though the cabinet height specified is 34.5 inch.

This might be a good time to discuss the detached toe base. In the *Standard Cabinets* directory there is a *Standard Detached Toe* cabinet. This is not some special cabinet but, in fact is made up of a standard cabinet, resized with some of the parts removed. You might want to load it and then pause the cursor over each part to see what it is.

Other than corner cabinets, you will find that all cabinets use the same set of parameters and differences in these cabinets are simply differences in size and parameter settings.

One additional point about the *Height* of a detached toe cabinet. When this cabinet is placed in a *Custom Layout*, it is located the specified height above the floor to make it easier to mate it with the detached toe base.

## ***Working with Global Settings***

There are times while working with a cabinet that you may want to change a certain parameters for every part in the cabinet. For example, you may want to change material or type of joint. This can be tedious if you need to access each part or, even worse, each joint on each part.

To make this easier, there is a *Global Settings* area in *Construction Settings*. In this area you can change parameters for every instance on the cabinet. The parameters that you can change globally are *Material*, type of joint *Construction* and details about dado joints, both full dados and blind dados.

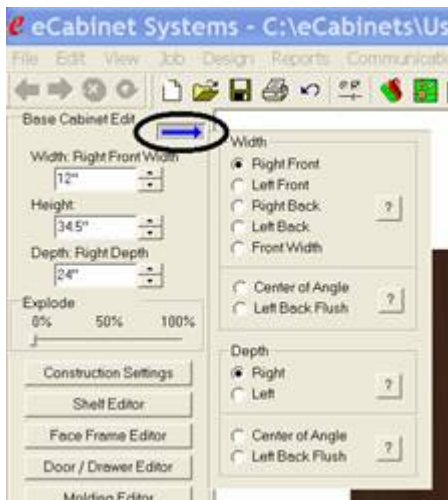

Changing the parameter here will change it everywhere on the cabinet.

Sometimes you want to change a parameter, material for example, everywhere except one area, the back for example. In this case, it is probably easier to change everything globally and then return to the back and change it individually then to change each component except the back individually.

Also note that should you begin to change a parameter and then determine that you really don't want to change it, there is a *no change* option that you can select. Once you begin working with a parameter you either need to change it or indicate that you want no change to it.

## Corner Cabinet Details

Corner cabinets are somewhat unique because they include parameters that other cabinet types do not share. These parameters are specific to the unique requirements of a corner cabinet.

The *Cabinet/Assembly Editor* for the corner cabinet is essentially the same as for the base or upper cabinet with two additions.

The first addition is a dialog to help define the basic dimensions of the corner cabinet. It is accessed by pressing the button with the blue arrow shown highlighted here.

This opens the dialog shown to the right of the arrow.

Base and upper cabinets have only three primary dimensions, *Width*, *Height* and *Depth*. Corner cabinets are more complex.

The way this dialog works is quite simple. Once you understand the concept behind it you will find it quite easy to use.

There are a lot more dimensions that must be maintained on a corner cabinet than on a standard base or upper cabinet.

Instead of adding a whole list of new dimension boxes for corner cabinets, the system keeps the same three dimension boxes, but uses a dialog to select which dimension on the corner cabinet is in those dimension boxes at any time. In the example shown, the top *Width* box is currently showing the *Right Front Width* of the corner cabinet. If you select another width for display, the title over the dimension will reflect that change.

In this way, all the various dimensions can be specified while maintaining the standard three dimension boxes.

The next obvious problem is what do all these dimensions mean?

To address this, a question mark button has been placed in each area which launches a diagram of the corner cabinet showing the meaning of each dimension name.

It is possible to specify any of the dimensions shown, however, in many cases the dimensions are interconnected. Changing one may change others, however this approach allows you to specify dimensions of the corner cabinet using the dimensions most available to you.

You will quickly notice that each side of the corner cabinet can be a different dimension, both in *Width* and *Depth*. With the other changes, you will find that corner cabinets can become somewhat complex. These are necessary to create the variety of corner cabinet designs required by most cabinet shops so we must learn to deal with the somewhat more complex approach.

The second area where corner cabinets differ from base and uppers is in *Construction Settings*. When you load a corner cabinet, one additional dialog area becomes available called *Corner Settings*.

There are three areas that are defined in the corner settings dialog.

Making a change to any of these automatically changes the corner cabinet you are working on.

The first area determines whether the cabinet has a *Corner Front* or an *Angle Front*. Again a question mark button brings up a diagram, as shown, to help

you understand the meaning

corner left the

of the terms used.

The next area determines if a cabinet with face frames has the left and right stile mitered parallel to cabinet sides as shown.

Obviously this only applies to *Angled* front cabinets since on *Corner Front* cabinets the face frame is always 90 degrees to the cabinet side.

If you select *Mitered*, the system will designate it as mitered but the display in the current version of the software does not show the miter.

The designation of *Mitered* is important when placing cabinets in a *Custom Layout*.

The face frame of the corner cabinet is going to butt against an adjoining cabinet. The point where this butt occurs is controlled by this miter setting.

If you indicate the sides are mitered, the corner cabinet will butt against adjoining cabinets at the point marked in blue. If, however, you do not check *Left and Right Sides Mitered*, the corner cabinet will butt against adjoining cabinet at the point marked in red. This will be easier to understand once the display properly shows the miter, however, for now the system does make proper use of this setting when placing cabinets, which is the important point.

The next selection is a checkbox that determines on a 90 degree corner cabinet with no *Corner Gap* (we will cover that in a minute), whether the two back panels overlap or are mitered.

mitered.

A 90 degree cabinet is the only angle at which this option exists. Otherwise, the back corner is always

If you select overlap, one back panel is cut shorter than the other, providing the overlap. This can be machined with only 90 degree vertical cuts.

If you select mitered, both panels are made long enough for the miter cut, however, the back edge of both panels must be mitered at the correct angle before the panels fit together at the back.

Here again, the actual miter is not displayed but the individual components are made long enough so that the miter can be cut on each.

For display purposes, they are meshed as shown.

The next parameter that *Angle*.

you can adjust is the *Corner*

This is simply the angle that the two back panels make with each other. Angles from 90 to 179 degrees are possible.

The final corner setting is the *Corner Gap*. Once a corner gap is specified, a third back panel is added.

The three back panels are always mitered.

Again, the actual miter is not displayed in the software but instead the parts are made large enough to accommodate the miter and then are meshed for display. Again you must realize that the proper miter angle must be cut on the part for them to assemble properly.

These are the basics of corner cabinets but, with these controls a huge variety of cabinets can be created.

## ***Using the Door/Drawer Editor***

### **Using the Door/Drawer Editor**

The *Door/Drawer Editor* has several functions including configuring and designing doors and drawer fronts, installing doors and drawer fronts and adding hardware. In the case of decorative hardware, you can specify mounting locations without actually adding the hardware and add it when the cabinet is used in *Custom Layout*. In this section, when we use the term “door” we generally mean doors and drawer fronts unless we specifically say something applies to only one.

The *Door/Drawer Editor* is accessed through an icon or menu selection from the *Cabinet/Assembly Editor Main* page. The door design and selection area, which is a sub area of the *Door/Drawer Editor* can also be accessed from other areas of the software when a door is required.

## **Designing Doors**

### **Designing Doors**

One section of the *Door/Drawer Editor* is used to configure and save designs for doors and drawers. These saved designs can then be used in the *Cabinet/Assembly Editor* or can be placed in a room in *Custom Layout*. This area is accessed by pressing the *Door/Drawer Selection* button from the *Main* page of the *Door/Drawer Editor*.

A concept you need to understand is the idea of a “default” door. From within the *Door/Drawer Editor* you do two things, you configure and save door and drawer front designs and you specify which design should be used when a door or drawer front is placed on a cabinet. The design you specify is the “default” design. This default door specification is part of the cabinet and is saved when the cabinet design is saved. When you reload a cabinet the default for that cabinet is re-established. If you add another door to the cabinet it will be that door.

There are four distinct door areas, *Conestoga*, *Thermwood*, *MDF* and *Slab*. We will examine these in this order.

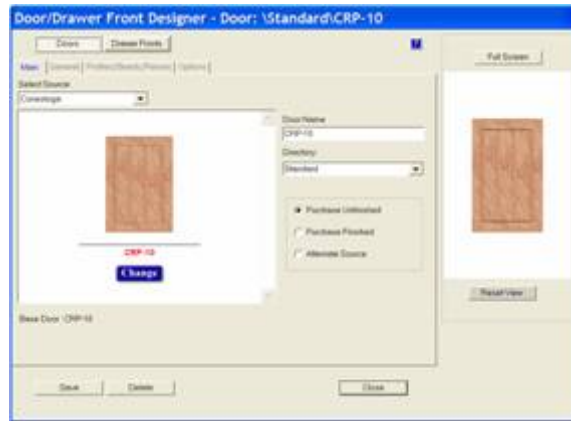

## Designing Conestoga Doors

Conestoga doors and drawer fronts are essentially designs developed by Conestoga, a leading cabinet door manufacturer. These can be configured by the software in pretty well every variation available from Conestoga and in addition to using these designs in your jobs, you can also purchase these doors through the program at an eCabinet Systems Member discount with very little additional effort.

From the *Main* page of the *Cabinet/Assembly Editor* click the *Door/Drawer Editor* icon, then click the *Door/Drawer Selection* button and select *Conestoga* and the *Standard* directory.

This brings up the design dialog shown above. Double click on a door design to load it for editing.

The selected door is shown in the working window and it is shown again in a small window to the right. The image in the window on the right can be moved, rotated and zoomed using the *Shift* key and the mouse.

The *Full Screen* button switches the door to a full screen view where it can also be rotated, moved and zoomed. When you do this, moving the cursor to the lower left pops up a menu you will need to get back.

A radio selector determines if the door is *Purchased Finished*, *Purchased Unfinished* or comes from an *Alternate Source*.

If you select *Purchased Finished*, the cost of a finished door purchased from Conestoga is added to the material cost for the cabinet each time a door is added and the appropriate size door is added to the *Buy List* and *Shopping Cart*.

If you select *Purchased Unfinished*, the cost of an unfinished door purchased from Conestoga is added to the material cost for the cabinet each time a door is added and the appropriate size door is added to the *Buy List* and *Shopping Cart*.

If you select *Alternate Source*, the door is added to the *Cut List* each time you add a door and the *Alternate Door Source Cost* defined in *Settings/Preferences* is used to add a cost for the door to the material cost for the cabinet.

The door cost added to the cabinet cost is the cost to purchase the door. There is a place in the *Define Costs* area of *Settings/Preferences* where you can “mark up” the basic purchase price of the doors and drawer fronts to allow for additional costs such as shipping. You should do this if you want an accurate estimate of the cost of doors and drawer fronts.

You may also notice in the Conestoga area, when you specify either *Purchase Finished* or *Purchase Unfinished*, door and drawer front sizes are automatically rounded to the nearest 1/16 inch. This is because Conestoga only builds doors in even 1/16 inch increments.

There is a final selection, *Build in House*.

It is clear that you cannot build Conestoga doors yourself. This selection is offered for those who build their own doors and allows them to use Conestoga doors for display purposes.

If *Build in House* is selected, neither the Conestoga cost calculation nor the *Alternate Source* cost is used. Instead, cost as determined by the material used and a listing of these materials is provided in the *Cut List*.

To make this accurate, you must specify certain parameters about how you make your doors. This done in a dialog that is accessed by pressing the *Details for Cut List* button.

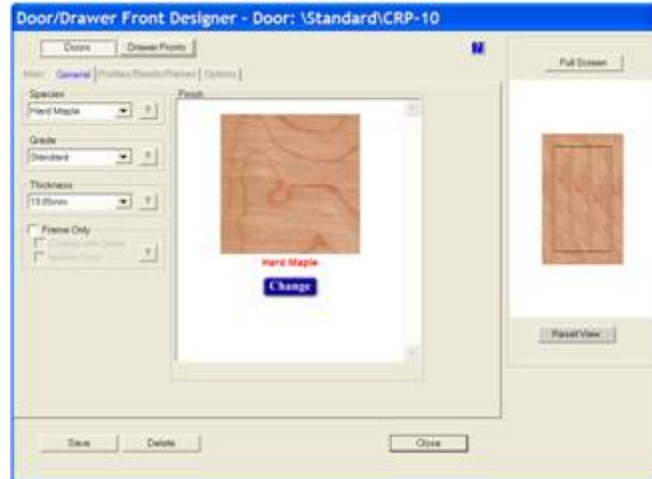

The various settings are obvious from the diagrams.

The area titled *Non-Thermwood Door Settings* should also be adjusted. When this dialog is accessed through the *Thermwood* door area, these settings have already been determined

during the design process and so do not need to be specified. When this dialog is accessed through the Conestoga door area, they need to be specified.

Now we will address configuring a door design. Note that we do not designate a size, only a design. The actual size is assigned when the door is actually used. This is also when the cost is calculated.

A series of tabs above the working window accesses various parameter areas that can be adjusted. Switch to *General* and the following appears.

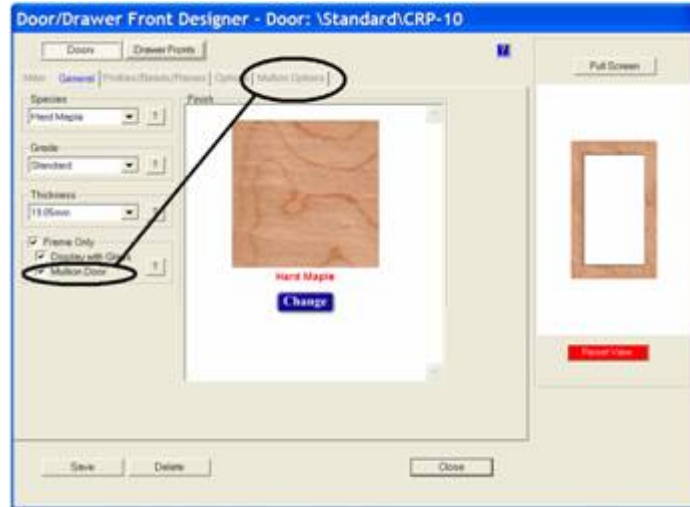

The *Species*, *Grade* and *Thickness* are selected along the left. The *Finish* that will be displayed is shown in the center graphic window. You can select from the available finishes for this species of wood by pressing the *Change* button.

Note that the view to the right does not automatically change when you change a parameter. Any time you want to view the changes you have made to the door, press the *Reset View* button.

The software includes the ability to create frame and mullion doors using a feature called *Frame Only*. Check this box to remove the center raised panel and specify a door that is only a frame.

Check *Display with Glass* to display the door with a transparent glass center panel.

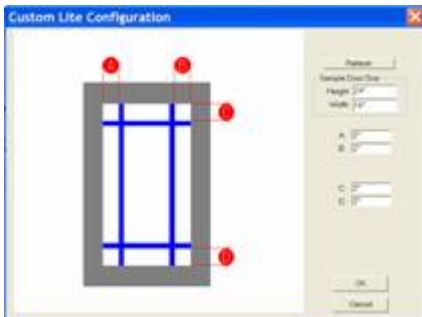

Check *Mullion Door* if there are horizontal and/or vertical mullions on the door. Checking *Mullion Door* adds another tab to the top which accesses an area where mullions are defined. Note that within eCabinet Systems the vertical and horizontal members are referred to as *Vertical* and *Horizontal Mullions* rather than mullions and muntings to avoid confusion.

There is a lot of flexibility in defining mullions. To understand this area better, be sure to press the question mark buttons to view diagrams of various parameters.

The first step is defining how many horizontal and vertical mullions are on the door using the input boxes.

At the bottom there are three choices for the *Lite Configuration*. The *Standard* and *Balanced* configurations are both defined vendor standards and require nothing more than selecting them. The *Custom* configuration, however, requires that the actual configuration be specified.

Once *Custom* is selected, it is then possible to create non-symmetrical left and right hand door. To do this, check *This Door is Handed* and select either *Left Handed* or *Right Handed*.

The *Lite Configuration* is specified using the *Set Configuration* button.

The dialog to the right is used to define the custom *Lite Configuration*. Note that the dimensions of the lites specified here do not change when the overall size of the door changes, however, the size of the lites not specified will change to accommodate changes in door size.

Now, let's return to the other tab selections beginning with *Profiles*, *Beads and Raises*.

This displays the current edge profile around the outside edge of the door, the current bead on the door

frame and the current raise on the center panel. To change any of these, press the *Change* button and a list of available options is shown. Note that there are different selections for different basic door designs. The software offers you only those choices of profiles that are available from Conestoga. Scan down the list and select the design you want. When you have made all your selections, press the *Reset View* button to see the door with the new selections.

This brings us to the last tab called *Options*. This area allows you to select a wide variety of options offered by Conestoga. The question mark button by each option explains exactly what it is. Note that these options will be added to any doors purchased through the program but, they do not display on the door, either here in the *Door/Drawer Editor* or in the *Cabinet/Assembly Editor* or *Custom Layout*.

Once the door design is complete, set the name and directory and press the *Save* button. Be sure to save the design BEFORE pressing *Set Default*. Once you press *Set Default*, the door will be used as the default door but is not saved and you cannot go back and save it without reconfiguring it from scratch. Even if you don't think you will need the design again, it is still a good idea to save it just in case.

Also, be sure that the file name and directory are correct BEFORE pressing the *Save* button. When you press *Save* it is saved under the name and directory currently displayed.

## Designing MDF Doors

MDF doors work like other doors in that we define a design, save it under a new filename and then make that filename the default so that design is used when we add a door.

MDF door design uses tool files (.tol) for the outside profile and inside shape. In designing an MDF door, we specify a tool for the outside profile. We then select a tool for the inside profile and define the path that this inside tool takes. This path is defined in the same manner as the Thermwood doors.

Note that the path defined using the definition tables is the path of the center of the tool.

Tool shape files (.tol) are available in the software for those profile tools that can be purchased through eCabinet Systems. In addition, there are several asymmetrical MDF door tools you can use to create modeled door designs that look very much like a five piece door. Use of asymmetrical tools is covered later in this section.

You can also create your own tool files using the *Shape Manager*. If you want to use a custom profile tool, you need to create it prior to starting the development of the MDF door. Now, let's design a door.

Start the *Door/Drawer Front Designer* (it will launch whenever you need to select a door or you can click on the *Door/Drawer Front Designer* icon from the top toolbar).

Under *Source* select MDF. Next we need to load an existing door. An *MDF Standard* door is available in the *Standard* directory if you have not saved any of your own designs yet. This is a basic door without any cuts or profiles.

This might be a good time to rename the door and specify the directory you want it saved in.

The *Material* selection allows you to select the sheet stock you want the door made from.

If you select *Build In House*, this is the material that the doors will be nested on.

If you select *Alternate Source*, the *Material* selection will define the color and texture used to display the doors but, the doors will not nest but will instead appear in the *Buy List*. Also, if you select *Alternate Source*, the *Alternate Source Door* pricing will be used to calculate cost for the doors.

As with the other types of doors, you have the viewing window to the right and the ability to see a full screen view of the design.

The process of configuring an MDF door consists of selecting the profile tool for the exterior edge and a tool for the interior profile. Then we specify a path for the centerline of the tool to develop the interior profile. Let's look at these steps, one at a time.

To select the profile tools, press the *Tools* tab.

Tools that can be purchased through the program are already available as .tol files as are some sample asymmetrical tools intended for MDF doors. They can be found in the *eCabinet/My Profile Tools/MDF Asymmetrical Tools* directory.

Custom tools for use here can also be created and saved in the *Shape Manager*. See the section *Using the Shape Manager* for detail instructions for creating custom tools.

Start with the exterior profile. Press *Select Tool*, then find and select the tool file you want for the exterior edge of the door. Press *View* to see an image of the tool.

At this point, we need to set the plunge depth. Most tools are designed with the zero point at the center bottom of the tool profile so plunge depth is a negative number for cuts into the part. When you enter a number and press *Apply* you will see the effect of the plunge depth.

The *Tool Diameter* is the diameter specified when the tool profile was created. The profile will be shifted away from the center of the part by half that diameter to just meet the edge of the part. If you check *Apply Radius Comp*, the tool will also be shifted at the machine to allow for any difference between the actual diameter of the tool used and the *Tool Diameter* specified here.

*Additional Offsets* are used to shift the tool either toward or away from the part by an additional distance for whatever reason you might want.

There is also a checkbox that determines how the system handles corners. This setting depends on how the door will be machined. If it is to be machined using a profile tool, leave the box unchecked and the corners will be rounded to represent the rounded corners that result from this type of machining.

If the center cut is to be modeled, check the *Miter Edges* box and the corners will be squared off to simulate the look that results from modeling. Note that when using an asymmetrical tool, the profile must be modeled so the *Miter Edges* box should be checked.

MDF doors use essentially the same tables as the Thermwood doors covered above. In this case, however, the path specified by the definition tables is the centerline path for a profile tool.

There are three types of center shapes that can be cut into an MDF door, *Square*, *Arch* and *Cathedral*.

A *Square* door essentially looks like a frame with a raised center panel. Stile and rail widths can be specified, although remember that the width specified here is the distance from the edge of the door to the center of the tool that cuts the center profile. The actual width of the stiles and rails will be less depending on the tool design. It does require that both stiles be the same width and both rails be the same width, however, the stiles can be a different width than the rails.

The second type of door supported is an *Arch* door. An *Arch* door has an arch cut into the top rail as shown to the right. The height of the arch is specified in the *Arch* input box. The arch is essentially a segment of a circle.

It is also possible to specify a side flat on each side of the arch as shown to the left.

This is specified in the table and the side flat can be made to vary with the width of the door. Note that the doors shown here all have the *Miter Edges* box checked.

Essentially the way this table works is that the software uses the door width to look up in the table the size of the side flats. The one caution is that if the door size qualifies for

more than one specification, the system will use the last entry in the table that the size qualifies for.

For example, if you set 0 to 17 inch as a 2" flat and 17 to 24 inch as a 3" flat on the next line, a 17" door qualifies under both specifications. In this case, the last entry, 17 to 24 inch gets executed. As a final note, set the entries in order, starting with the narrowest and ending with the widest, otherwise the system gets confused.

*Preview Size* lets you specify the size of the door shown in the preview window. By changing this size you can see the basic effect of the entries in the table. Be sure to press the *Reset View* button each time you make a change to see the effect of the change.

The final and most complex door is the *Cathedral*. A *Cathedral* door has a center arch with two reverse arches, one on each side. The radius of each reverse arch is expressed as a percentage of the radius of the center arch. All three arches are adjusted to meet this ratio requirement while achieving the arch height specified.

Setting parameters for a *Cathedral* door is the same as setting parameters for the flats on an *Arch* door. You specify a width range and then specify the settings for any door that falls in that range.

In addition to the minor radius, you can also specify side flats and a top flat for a *Cathedral* door. The door to the right has one and a half inch side and top flats.

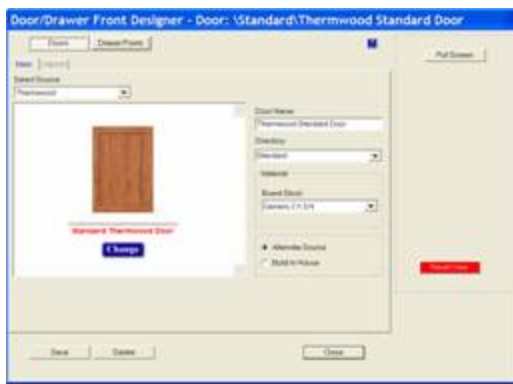

You might also note that when displaying MDF doors that have a grain, the grain runs the same direction across the entire door as it would if it were made from a single piece versus the grain running in a different direction for stiles and rails as it does when making a five-piece Thermwood door. This simulates the appearance you would get from laminating a foil over a machined door.

## Designing Thermwood Doors

The next type of door supported by the software is a generic five piece door. This area is derived from a five piece door system Thermwood developed for its CNC routers. This is a flexible system that allows the design of three different kinds of doors, defined primarily by the shape of the center raised panel. Doors can have a square center panel,

an arched top, with or without end flats or a cathedral top, again with or without end flats and a center flat.

You can also define the width of the stiles and rails.

This combination offers a lot of flexibility and can generally reproduce almost any door design.

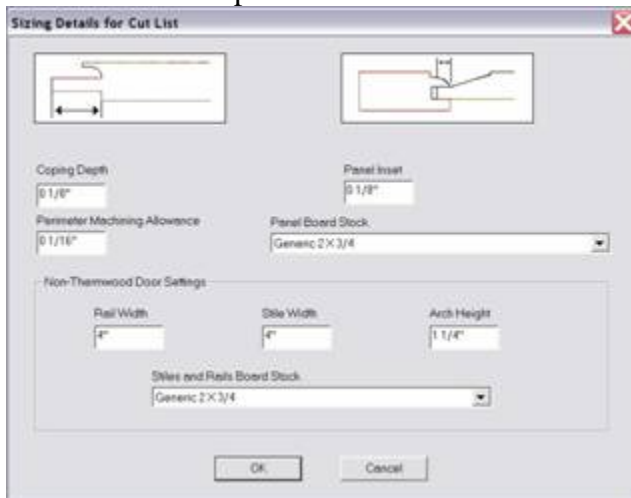

There are two ways to obtain these doors, you can buy them from someone else, in which case this area is used to display the doors or you can make them yourself.

If you plan to buy the doors from others, check *Alternate Source*.

When you check *Alternate Source*, alternate source costing is used to calculate the cost for the door.

If you plan to build the door yourself check *Build in House*.

If *Build in House* is selected, cost as determined by the material used and a listing of these materials is provided in the *Cut List*.

To make this accurate, you must specify certain parameters about how you make your doors. This done in a dialog that is accessed by pressing the *Details for Cut List* button.

The various settings are obvious from the diagrams.

The area titled *Non-Thermwood Door Settings* does not need to be adjusted. When this dialog is accessed through the *Thermwood* door area, these settings have already been determined

during the design process and so do not need to be specified. This area is provided so that when this dialog is accessed through the Conestoga door area, they can be specified.

A standard interior bead and raise profile are used for these designs and tooling to reproduce these is available. Thermwood plans for output from these door designs to be sent to its CNC routers where the individual components can be machined using this tooling.

This area relies on a basic approach which, once understood, is simple and straightforward. The door design contains a table which defines certain dimensions. This is basically a “look-up” table based on the width of the door. The system looks at the door width and then uses the dimensions specified for that width.

Our job in defining the door is to develop this table, specifying what we want at each door width.

From *Select Source* select *Thermwood* and the dialog appears.

From this page select a material from the available *Board Stock* materials. This is primarily used to define a texture or image for the door. The image associated with the material selected is the image used on the surface of the door.

Selecting the *Layout* tab accesses a dialog where the layout or geometry of the door is specified.

There are essentially three types of door supported.

A *Square* door is essentially a frame with a raised center panel. Stile and rail widths can be specified, although it does require that both stiles be the same width and both rails be the same width, the stiles can be a different width than the rails.

circle.

The second type of door supported is an *Arch* door. An *Arch* door has an arch cut into the top rail as shown to the right. The height of the arch is specified in the *Arch* input box. The arch is essentially a segment of a

It is also possible to specify a side flat on each side of the arch as shown to the left.

This is specified in the table and the side flat can be made to vary with the width of the door.

Essentially the way this table works is that the software uses the door width to look up in the table the size of the side flats. The one caution is that if the door size qualifies for more than one specification, the system will use the last entry in the table that the size qualifies for.

For example, if you set 0 to 17 inch as a 2" flat and 17 to 24 inch as a 3" flat on the next line, a 17" door qualifies under both specifications. In this case, the last entry, 17 to 24 inch gets executed. As a final note, set the entries in order, starting with the narrowest and ending with the widest, otherwise the system gets confused.

The *Preview Size* is the size door shown in the preview window. By changing this size you can see the basic effect of the entries in the table. Be sure to press the *Reset View* button each time you make a change to see the effect of the change.

The final and most complex door is the *Cathedral*. A *Cathedral* door has a center arch with two reverse arches, one on each side. The radius of each reverse arch is expressed as a percentage of the radius of the center arch. All three arches are adjusted to meet this ratio requirement while achieving the arch height specified.

Setting parameters for a *Cathedral* door is the same as setting parameters for the flats on an *Arch* door. You specify a width range and then specify the settings for any door that falls in that range.

In addition to the minor radius, you can also specify side flats and a top flat for a *Cathedral* door. The door to the right has one inch side flats and a one inch top flat.

When you are finished with the door, return to the *Main* page, enter a directory and door name and press *Save*. This saves the door design so that it can be accessed when needed.

## Designing Slab Doors

The simplest type of door supported is the *Slab*. A *Slab* door is nothing more than a rectangular piece of sheet material surrounded by an edge band. Again, the image associated with the material and the edge banding selected is used to display the door.

If you select *Build in House*, the *Slab* doors and drawer fronts will be nested on the material they are made from along with any other components made from that material. If you select *Alternate Source*, the *Slab* doors and drawer fronts will not be nested.

Remember that the core of the *Slab* doors and drawer fronts will be reduced in size to allow for the thickness of the edge banding. If you do not want the door size reduced for edge banding, specify an edge banding material that has a zero thickness.

The software offers some interesting features for cabinets with slab doors.

First, you can control the wood grain direction on the front of the door. Right click in the *Door/Drawer Editor* and select *Construction Settings*. In the *Add Door/Drawer Settings* area, specify the grain direction. Set this, then return and add the door.

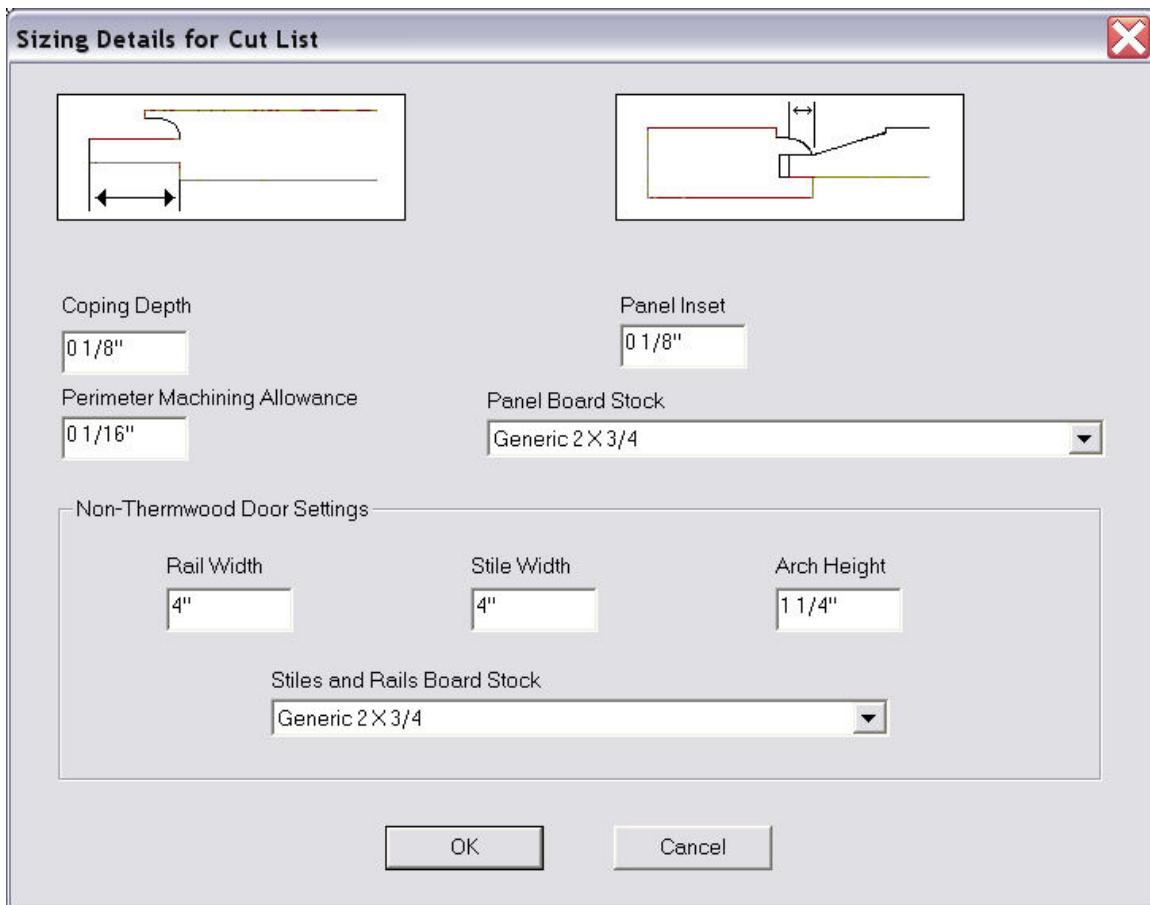

Another great tool in the *Main* area of the *Cabinet/Assembly Editor* is the *Group Parts* feature. Using this you can group a series of slab doors and drawer fronts so that they keep their relative position with respect to each other when they are nested. They are nested as a group. In this way, the wood grain flows across all the grouped parts giving a rich “high end” look.

From the *Main* page, Right click and select *Group Parts*. Then, click on each of the door and drawer fronts you want included in the group.

## Five Piece Door Cut List Detail

eCabinet Systems offers the user an ability to define necessary details about five piece doors required to give accurate part breakdown in the Cut List when the door/drawer front is designated as Build In House..

When in the Door/Drawer Front Designer, with a Five Piece Door/Drawer Front designated as Build In House loaded, click on the Details for Cut List button. This dialog will open where the necessary additional data can be provided. With this data provided the door/drawer front can be saved and anytime it is used the Cut List will show a breakdown with the necessary dimensions for all parts.

## Placing Doors and Drawer Fronts

The basic idea is quite simple, first select a default door design then click and highlight the area where you want the door and click on the type you want, *Right Hinge, Left*

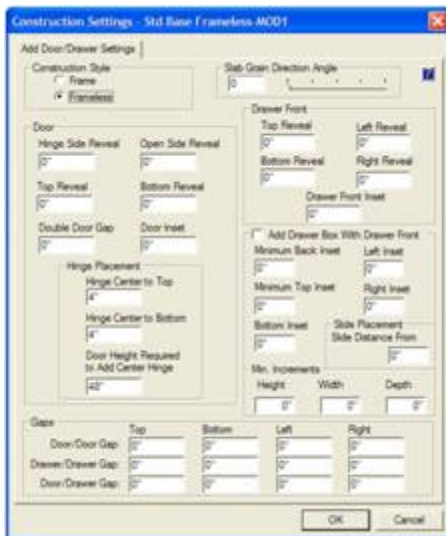

*Hinge, Double or Drawer.* There are however, quite a few parameters needed to add a door to a cabinet. As with everything in the software, there is a set of parameters that define how a door or drawer is added to a cabinet.

These parameters are set in the *Construction Settings* area under *Add Door/Drawer Settings*. From the *Main* page of the *Cabinet/Assembly Editor* right click and select *Construction Settings*. Then, select *Add Door/Drawer Settings*.

You can also access this from the *Door/Drawer Editor* by right clicking and selecting *Construction Settings*. If you select it from the *Door/Drawer Editor* you will automatically be in *Add Door/Drawer Settings*.

When you change parameters in this area, they remain until you change them again. They do not affect existing doors but do define how new doors are added (unless, of course, you highlight a door before making the change).

You are also offered the opportunity to override these parameters each time you add a door. If you override the parameters when you install a door, they are only changed for that ONE DOOR. Parameters in *Construction Settings* remain unchanged.

Therefore, if you want to adjust parameters for all the doors you plan to add, change the parameters in the *Construction Settings* area. If you want to change parameters for only one door, override the parameters during the installation process.

*Construction Settings* and cabinet defaults like hinges, pulls, door designs, etc. are maintained with the cabinet itself. Loading a cabinet also loads the settings and the defaults that existed when the cabinet was saved.

Note that there are two sets of *Add Door/Drawer* settings, one for frame and one for frameless. If the cabinet you are mounting the doors on is frameless,

the frameless settings are used. If the cabinet is a face frame cabinet, the Frame settings are used.

Most of the settings are easy to understand. We will defer the drawer box settings which are covered in detail in another section of this manual that deals with placing drawer boxes drawer fronts. For the settings we will cover here, the one area that can be a little confusing is *Gaps*, so let's look at it in more detail.

The system allows you to install more than one drawer or more than one door in a highlighted opening.

When you install multiples, gaps are used to separate them.

If you install a double door, the *Double Door Gap* (found in the *Door* area) is used for the vertical center gap. If you install one double door over another, that is two high, in a single opening, the gap as set in *Door/Door Gap* is used between them horizontally but the *Double Door Gap* is used between them vertically.

Because each side of doors and drawers can be assigned a different gap, they may come into conflict at times. Perhaps we set the *Top* gap for a door as .125", and the *Bottom* gap at .25". If we then put the two doors together, one gap says to make the separation .125" but the other gap says to make the same separation .25". When this occurs, the system uses the largest gap, .25" in this case.

There is one other case where these gaps come into play and that is when placing doors and drawer fronts on frameless cabinets with shelves or partitions.

In the view to the left, we have added a door with a zero reveal to the opening on the left. As you can see, the door completely overlaps the center partition.

If we now try to add a similar door, also with a zero reveal, to the right opening, it would need to overlap the partition all the way to the left surface. This would mesh the two doors and is clearly unworkable.

To address this, the software uses the *Gap* settings to resolve the conflict.

The image to the right shows the two doors. Notice that the gap has been located in the center of the partition and both doors resized to achieve the specified gap.

This approach makes placing doors and drawers on frameless cabinets quite a bit easier. Just set the gaps to what you want over shelves and partitions and place the doors and drawers.

There may be times where you may want to specify the exact positioning of the gap over a shelf or partition. Perhaps you want the gap to be positioned at other than the centerline of the shelf. In this case, set the gap for both doors or drawers to zero. When this occurs, the doors and drawers obey the reveal dimensions, even if this results in the two components meshing. If you set the *Gaps* to zero, you are in charge of the positioning of the joint and need to focus on this area carefully to prevent developing a design that cannot be produced.

The program does not perform the same function for face frame cabinets where overlaps rather than reveals are used to specify placement.

Also, an understanding of how the software uses overlaps and reveals might be useful, especially when working with more complex structures that combine face frames and frameless on the same cabinet. Since these cabinets do occur, a basic understanding might be useful.

The key to understanding how doors and drawers are placed in the opening is the highlight area. When you click on an open area, the software looks around and tries to determine what you want. It then highlights the area it thinks you want to put a door or drawer over.

The frameless cabinet to the left shows such a highlight. The center shelf is fixed so the area above or below the shelf can be selected. If you want a door to cover a fixed shelf, the door must be added first and then the shelf added behind it.

Adjustable shelves are always ignored during the selection process and doors always cover adjustable shelves.

Now, focus on where the highlight ends. This is where the software sees the limit of the opening. It then looks at the reveal numbers for this door and measures from the edge of the highlight.

For frameless, it takes the thickness of the side, subtracts the reveal and adds the result to the highlighted area to determine the edge of the door.

The frame cabinet shown works much the same way. The system takes the size of the highlighted opening and adds the overlaps to determine the size and placement of the door.

Therefore, the key to understanding how the door will fit the cabinet is to analyze the highlighted opening. If *Has Face Frame* is checked in the *Construction Settings- Face Frame* dialog, even if every piece of the face frame has been deleted, it is a face frame cabinet. In this case, *Overlaps* will be used. If *Has Face Frames* is not checked, it is a frameless cabinet and *Reveals* are used.

Adding doors and drawers is then straightforward, simply highlight the opening and press the appropriate button. Adding more than one door or drawer to an opening however, needs further explanation.

The software allows you to add a stack of more than one door or drawer vertically to an opening. For example, you can place several drawers in a single opening.

If each of these is the same height, it is quite easy. Simply indicate the quantity at the top when the installation dialog appears and press OK. If you want to stack drawers or doors of different height it is slightly more involved but still not all that difficult.

In this case, you will need to add each different sized drawer one at a time.

Leave the quantity as “1” and set the height of the first drawer (note this also works for doors). Then you must decide whether you want the resulting opening at the bottom or top. If you set *Adjust Bottom* the drawer will be placed at the top of the highlighted opening and the remaining opening will be left at the bottom. If you select *Adjust Top*, the drawer is placed at the bottom of the highlighted opening and the remaining opening is left at the top.

You can, at any time, add multiple drawers of equal height to an opening but this will fill the entire opening. You cannot leave a gap when doing this.

## Adding Drawer Boxes along with Drawer Fronts

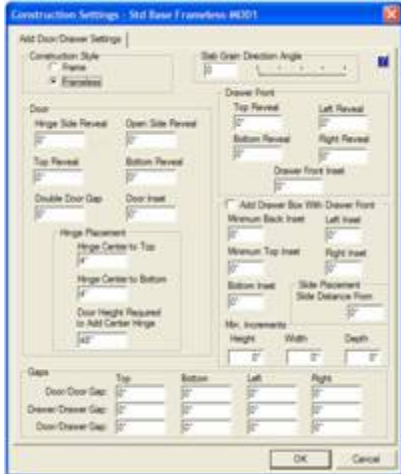

When a drawer front is added to a cabinet you can also add a drawer box behind the drawer front at the same time. As with door and drawer front designs, a drawer box needs to first be designed and saved and then designated as the “default” drawer box. Before we begin, let’s take a quick overview of drawer boxes.

Once a drawer box has been configured and saved (See *Designing Drawer Boxes* in this manual), there are three ways it can be added to a cabinet or assembly. These are done from the *Cabinet/Assembly Editor*.

- It can be added to and made part of a cabinet along with a drawer front in the *Door/Drawer Editor*. It will then automatically resize with the cabinet.
- It can be added to and made part of a cabinet without a corresponding drawer front using the *Drawer Box Editor*. It will automatically resize with the cabinet.
- It can be added to the workspace as a *Display Item* where it will be saved with and reload with an assembly. It can be *associated* to a cabinet where it will save with and reload with the cabinet but will not resize with the cabinet. It must be part of the cabinet and not just associated with it to resize.

In this area we will cover adding a drawer box to a cabinet along with a drawer front using the *Door/Drawer Editor*.

Before we can add a drawer box, we must design and save one. This is done using the *Drawer Box Designer*. This process is covered in detail in the *Designing Drawer Boxes* area of this manual. For this discussion we will assume we have already configured and saved our drawer box design and we will focus on installing the drawer box along with a drawer front.

As with doors and drawer fronts, there are two places where we define how drawer boxes are added. In *Construction Settings*, as part of *Add Door/Drawer Settings*, there is an area where we can set the default installation settings for a drawer box. Then, as we actually install a drawer box in the *Door/Drawer Editor*, we are presented with the dialog shown where we can modify the settings we placed in *Construction Settings* for this one installation.

Basically the *Construction Settings* are used unless we specifically change them during installation.

There is one more note that might help avoid confusion. If you access *Construction Settings* from the Main page you may note that there is an area in *Construction Settings* titled *Add Drawer Box Settings*. This particular area is for use with the *Drawer Box Editor* and is specifically for drawer boxes added WITHOUT drawer fronts. Settings for drawer boxes added WITH drawer fronts are found in the *Add Door/Drawer Settings* area.

Let's look at the installation parameters for a drawer box.

There are three basic types of settings for the drawer box. The first area defines insets. These are actually clearances from the cabinet to the drawer box.

The second parameter specifies how high from the bottom edge of the drawer side the drawer slide is located. This is also the zero point for the mounting hole pattern for the slide. This information is needed so that the mounting hole pattern can be added to the drawer box side and the cabinet end.

The next area is for specifying overall dimension "increments". This might take a little explaining. Some people like to build drawer boxes in fixed increments, that is they want the dimensions to be in even 1/32, 1/16 or 1/8 inch increments instead of building random sized boxes. This area allows you to specify the increment you want drawer boxes built in.

When increments are specified, the system will always round down to the next increment. Also, the insets or clearances specified are now minimum insets and the actual inset may be slightly larger when a dimension is rounded down.

The process of adding a drawer box with a drawer front is easy. From the *Door/Drawer Editor* press *Add Drawer*. Then in the dialog make sure *Add Drawer Box* is checked. At this point you also have the opportunity to modify the settings for this one installation. The settings that are presented to you are the ones you set in the *Add Door/Drawer Settings* area of *Construction Settings*. Once the settings are correct, press *OK*.

## Placing Doors on Corner Cabinets

There are two types of corner cabinets. An angle front cabinet has a single angled opening that goes between the two wings. Placing doors on an angle front corner cabinet is essentially the same as placing them on a base or upper cabinet.

The second type of corner cabinet, the corner front, has two surfaces at an angle to each other. There are some additional considerations when placing doors on this type of cabinet.

Begin by noticing that you can highlight each front face of the cabinet separately. Doors are installed in each of these openings separately.

The sequence you use to install the doors in these openings determines how they fit and overlap in the center. Let's look at the various options available.

If you install the doors, one at a time, the first door installed goes all the way to the corner and the second door is made shorter to overlap the first.

installed first and then the right installed.

For the cabinet shown on top, the left door was door was

On the bottom cabinet shown the right hand door was installed first and then the left door was added. Notice that this time the left door overlaps the right hand door.

In either of these cases, the gap between doors is the *Door to Door Gap* set in *Door/Drawer Settings*.

The software also allows for a *Double Right* or *Double Left* door. These are doors hinged on the right and center or hinged on the left and center.

They open on either the right or the left with the second door attached by a hinge to the first door.

The result of adding this type of door is shown here.

The gap where the corners of the doors meet and the method of measuring the gap are shown to the left.

The *Door to Door Gap* specified in the *Door/Drawer Settings* is measured from the corner of each door to the theoretical point at which the faces of the door intersect.

Another option for corner cabinets is a *Lazy Susan* door.

A *Lazy Susan* door is normally an inset door in which both doors are permanently attached to the Lazy Susan.

The actual placement and spacing is the same as for a *Double Right* (or *Left*) door.

You must specify an inset for a *Lazy Susan* door and allow sufficient gaps for the door to clear the ends or face frame when the Lazy Susan is rotated.

The primary difference in a *Lazy Susan* door is that no hinges are added to the cabinet for the doors, even if default hinges are specified.

In the case of a *Double Left* or *Right* door, only the primary hinges for the door that attaches to the cabinet are automatically added to the *Buy List*.

The hinge arrangement required between the doors must be added separately using the *Add Item* function.

The final type of door that can be added to a corner cabinet is a *Double Door*.

These are added in much the same manner as a single door, highlighting one side at a time and adding the door.

As with the single door, the side added first goes all the way to the corner and the side added last overlaps the first.

## ***Drawer Boxes***

### **Drawer Boxes**

The software supports the design, display and manufacture of drawer boxes. Drawer boxes can be stand alone items or can be made part of a cabinet.

Drawer boxes work similar to doors in that first you design and save them as a file and then use the saved designs. There are three areas in the software where saved drawer boxes are used:

- They can be automatically installed along with drawer fronts in the *Door/Drawer Editor*. In this case they are part of the cabinet and automatically resize with the cabinet.
- They can be installed directly in a cabinet opening without a corresponding drawer front using the *Drawer Box Editor*. In this case they are part of the cabinet and automatically resize with the cabinet. Note that the fronts of the drawer boxes can be inset so that a door can be installed in front of the drawer stack.
- Drawer boxes can be loaded into the *Cabinet/Assembly Editor* or into *Custom Layout* as a *Display Item*. In this case, they are not part of a cabinet and even if you associate them with a cabinet they will not resize when the cabinet size is changed.

This can get a little confusing so you might want to make sure you understand the above before proceeding. If the drawer box is installed with a drawer front in the *Door/Drawer Editor* or if it is installed directly into the cabinet box using the *Add Drawer Box Editor*, it becomes part of the cabinet and resizes automatically when the cabinet size changes. If it is used as a *Display Item* it does not resize.

### **Designing Drawer Boxes**

Drawer boxes are designed in an area called *Drawer Box Designer*. This is actually a stripped down version of the *Cabinet/Assembly Editor* configured specifically to design drawer boxes. Many of the controls are the same.

As with cabinets, you start with an initial “seed” drawer box, modify it and then save it under a new name. The modified drawer box can then be loaded, further modified and saved under yet another name. Unlike cabinets, however, drawer boxes can be saved and retrieved from any directory so it is important to remember where you put them.

Also unlike the *Cabinet/Assembly Editor*, the *Drawer Box Designer* only has two ways to modify the box, change the size or modify drawer box *Construction Settings*. There are no *Editors* since, unlike a cabinet, there is nothing extra to add or configure on a drawer box. The *Drawer Box Designer* has its own *Construction Settings* that pertain to drawer box design and construction. As with cabinets, each drawer box has its own *Construction Settings* that are part of the drawer box itself and define that particular drawer box.

The *Drawer Box Designer* is accessed from pretty well anywhere in the software through an icon in the top toolbar.

If you are in the *Door/Drawer Editor* or in the *Drawer Box Editor*, you can access the *Drawer Box Designer* using the button *Drawer Box Selection*.

If you are loading drawer boxes into the *Cabinet Assembly Editor* workspace using *Load Item – Drawer Boxes*, you can access the *Drawer Box Designer* through the button *Select Drawer Box*.

In short, any time you need to add a drawer box, the *Drawer Box Designer* pops-up where you can either load and use a drawer box design you previously saved or load a saved design and modify it into a new one. Now let’s look at the operation of the *Drawer Box Designer*.

The process starts by loading an existing drawer box. There are two initial drawer boxes that are part of the system. Each can be modified and saved under new filenames. They are found under *eCabinets/drawers/Saved/Slab/Standard*. Unless you save a modified drawer box to another directory the system should take you to the above directory.

The two standard drawer box designs offered represent the two basic ways dovetail drawer boxes are made. Both use a bottom material that is not as thick as the sides and is full dadoed into the front and sides. One box also full dadoes the bottom into the back, completely capturing it. The second design stops the back short so that the drawer bottom can be slid into the box from the back and pin nailed or stapled in place.

This second design allows the bottom to be removed for finishing the interior of the drawer box, eliminating blow back from the spray gun. The drawer bottom is then assembled and stapled in place after finishing.

Once the standard design is loaded we have a workspace that functions the same way as the *Main* page of the *Cabinet/Assembly Editor*. The drawer box image can be moved, rotated and zoomed using the same mouse controls as the cabinet (*Shift* + Left Mouse

Button to rotate, *Shift* + Right Mouse Button to move and *Shift* + Both Mouse Buttons to zoom). Note that the cursor needs to be inside the workspace window for these controls to work.

Also, the drawer box can be exploded using either the slide bar control or the wheel on your mouse. *Reset View* also works the same and you can use the arrow keys just like the *Cabinet/Assembly Editor*.

Workspace controls are also the same as the *Cabinet/Assembly Editor*. There is a slider to darken the background. There is also grid and axis designator controls available by right clicking and selecting *Grid Settings*. Please refer to these controls in the *Cabinet/Assembly Editor* area for details of their operation.

The drawer box *Width*, *Height* and *Depth* refer to the size drawer box that is displayed and saved. This size will generally be adjusted when the drawer box is actually used, so select a size here that is typical of what you might need.

The drawer box is initially presented to you in the same orientation as it would be placed in a cabinet. You are looking at the front of the drawer box as you look at the front of the cabinet. The front is the panel that is facing you. The back is the panel away from you that would be in the back of the cabinet.

From this, the left side, right side and bottom are easy.

Details of the drawer box are adjusted by right clicking and selecting *Construction Settings*. As with the cabinet, if you right click on a particular component, *Construction Settings* open to that area. Otherwise you reach each area by clicking on the top tabs.

There is also a *Construction Settings* icon on the small toolbar at the top which will open *Construction Settings*.

Let's start with the sides. Go to the *Left Side* area of *Construction Settings* (the *Right Side* area is identical). You will notice in *Construction* that in addition to the normal joints there is also a *Dovetail* joint. Dovetail drawers are considered high quality and we have developed a method of making these and machining them in a nest using a Thermwood CNC router with all machining begin performed from the top in a nest. This requires a special dovetail tool that includes a radius at the top. This top radius mates with the curved inside corner that results from machining the mating part using a small diameter straight cutter.

The tools required for this are available through the program.

Insets modify the side from its normal size. Positive insets make the dimension smaller and negative insets make it larger. When a drawer box is resized, the inset is based on the new size. For example, if you set a 1" inset for the top, the top will be 1" shorter than the normal height of the drawer box, regardless of what that height is.

The overlap between the sides and the front and back are specified in the front and back areas. A diagram is shown which represents the drawer as viewed from the top. The vertical pieces are the sides and the horizontal pieces are the front or back.

This can get a little confusing because the overlaps are specified in the front and back areas but the joint (construction) is specified in the left and right side areas.

Normally you will want front and back flush for dovetail joints and side flush for blind dado and other joints. Again, when we say “back flush” it means that the back overlaps the sides. When we say “side flush” it means the side overlaps the back.

Most drawer boxes use a thin bottom that is full dadoed into the sides, front and back. For drawers with a thick bottom, blind dado construction works well. In this case, you might want to go to the *Bottom Construction Parameters* and set all the tenon insets to zero in the *Placement* area. This creates a bottom that is similar to a raised panel as shown.

Now let’s address *Construction Parameters*. *Construction Parameters* are the details concerning geometry of the joints.

Each drawer box component has its own *Construction Parameters* and you can adjust each independently. You can also go to the *Global Settings* area and adjust certain parameters for every joint on the box. If you wish to change every parameter except one, it might be easier to change them all in *Global Settings* and then go back and adjust the one part that is different.

Except for dovetail settings, *Construction Parameters* are the same as found in the *Construction Settings* area of the *Cabinet Assembly Editor*. The *Construction Parameters* here however, only apply to drawer boxes. Changing a setting here does not affect the same setting as it applies to cabinets.

For full dado, blind dado and KD/RTA joints, we refer you to the description found in the *Cabinet/Assembly Editor* area. Although these settings only affect drawer boxes, they function the same way here.

Dovetail settings are grouped into two areas. The top area defines the placement of the dovetail tabs along the edge. The bottom area defines the geometry of the dovetail joint itself. For purposes of this manual we will refer to the male portion of the dovetail as the “tab” and the female pocket into which it fits the “socket”.

In defining placement along an edge, we will define the point at which the first dovetail starts from the edges of the part. We define the width of the pin. We also specify the maximum distance we want between pins. As the part size grows, the system separates the pins farther and farther apart, keeping the pin width the same. When the maximum

separation distance is reached, the system adds another pin and reduces all separations accordingly.

The *Front Inset* and *Back Inset* define how far from the front and back edges to the beginning of the first pin. This distance remains the same regardless of changes in size.

You will notice that there are settings for the top, bottom, front and back edges. The software supports dovetail joints on all four edges of each part, however, for drawer boxes you will normally only deal with the front and back edges. You do however, need to input valid dimensions for all four edges or the system will not allow you to proceed.

The final placement dimension you need to define is called *Max Distance Between*. This is the maximum distance between pins, as measured from center to center. The actual center to center distance may be smaller than this, but will never be larger.

Next, we must define the geometry of the dovetail itself. This is done at the area at the bottom. While you are free to put any dimensions you want here and they will display properly, to actually machine the joint the dimensions must correspond to a specific dovetail tool set.

In order to machine dovetail joints in a nest, a special dovetail tool is needed that has a radius at the top. This means that each tool only works for a specific dovetail depth. The top radius also corresponds to the radius of the straight tool used to machine the pin. Dovetail tool sets are available through the program, which include the correct settings for this area.

The one dimension you can freely adjust, in addition to pin (dovetail) width, is the *Corner Angle*. This is the angle on the pin. Here you see the same joint, the first with a 40 degree angle and the second with a 10 degree angle. As you see, the overall pin width stays the same, so to maintain the strength necessary you may need to adjust *Dovetail Width* with higher angles.

As with other areas of the software, use the display to view each change as you make it and adjust parameters until you get what you want.

## Using the Drawer Box Editor

Once a drawer box has been configured and saved (See *Designing Drawer Boxes* in this manual), there are three ways it can be added to a cabinet or assembly. These are done from the *Cabinet/Assembly Editor*.

- It can be added to and made part of a cabinet along with a drawer front in the *Door/Drawer Editor*. It will then automatically resize with the cabinet.

- It can be added to and made part of a cabinet without a corresponding drawer front using the *Drawer Box Editor*. It will automatically resize with the cabinet.
- It can be added to the workspace as a *Display Item* where it will be saved with and reload with an assembly. It can be *associated* to a cabinet where it will save with and reload with the cabinet but will not resize with the cabinet. It must be part of the cabinet and not just associated with it to resize.

In this area we will cover adding a drawer box to a cabinet using the *Drawer Box Editor*. This editor is used when we want to add drawer boxes to a cabinet opening without adding corresponding drawer fronts.

From the *Cabinet/Assembly Editor* with a cabinet loaded, you reach the *Drawer Box Editor* either using the icon in the top toolbar or by right clicking and choosing *Area – Drawer Box Editor*.

Before we start we must select the drawer box we want. Press *Drawer Box Selection* to launch the *Drawer Box Designer*. Operation of this area is covered in a separate area of this manual.

At this point you must load a drawer box design. You can modify it if needed. You also do not need to worry about size since it will be sized automatically for the cabinet.

When the drawer box you want is displayed, press *Set Default*. This design will then be used whenever a drawer box is added until you change it. If you want two different drawer boxes on the same cabinet, load the first and set it as the default. Add it to the cabinet. Then, press *Drawer Box Selection* again, load the second design, set it as the default and add it to the cabinet. Each drawer box is a different design.

There are a series of parameters that define how a drawer box is added.

In the *Construction Settings* for this cabinet there are two areas that define this. In the *Add Door/Drawer Settings* area, there is a section that defines a drawer box that is added in conjunction with a drawer front. These settings are used when a drawer box is added in the *Door/Drawer Editor*.

There is also a separate area called *Add Drawer Box Settings* which defines a drawer box that is added in the *Drawer Box Editor*.

Remember, to add a drawer front with a corresponding drawer box, use the *Door/Drawer Editor*. To add a drawer box without a front use the *Drawer Box Editor*.

The parameters from each of these areas are presented to you each time you add a drawer box. You are then given the opportunity to modify them for this one installation if you want. Any modifications you make during the installation process do not change the

parameters you set in *Construction Settings*, they only affect this one drawer box. Therefore the best approach is to set the parameters in *Construction Setting* to the most common parameters you use and then modify only those that need to differ when you install them.

Let's look at the installation parameters for a drawer box.

There are four basic types of settings for each drawer box. The first area defines insets. These are actually clearances from the cabinet to the drawer box.

The next area is for specifying overall dimension "increments". This might take a little explaining. Some people like to build drawer boxes in fixed increments, that is they want the dimensions to be in even 1/32, 1/16 or 1/8 inch increments instead of building random sized boxes. This area allows you to specify the increment you want drawer boxes built in.

When increments are specified, the system will always round down to the next increment. Also, the insets or clearances specified are now minimum insets and the actual inset may be slightly larger when a dimension is rounded down.

The third parameter area specifies how high from the bottom edge of the drawer side the drawer slide is located. This is also the zero point for the mounting hole pattern for the slide. This information is needed so that the mounting hole pattern can be added to the drawer box side and the cabinet end.

The final parameter is the *Drawer Box to Drawer Box Gap*. This is used whenever more than one drawer box is added to an opening.

The process of adding a drawer box is easy. Highlight the opening and press *Add Drawer Box*. You are again presented with the installation parameters which you can modify if necessary.

The software allows you to add a stack of more than one drawer box vertically to an opening. You can place several drawers in a single opening.

If each of these is the same height, it is quite easy. Simply indicate the quantity at the top when the installation dialog appears and press OK. If you want to stack drawers of different height it is slightly more involved but still not all that difficult.

In this case, you will need to add each different sized drawer one at a time.

As an example, leave the quantity as "1" and set the height of the first drawer. Then you must decide whether you want the resulting opening at the bottom or top. If you set *Adjust Bottom* the drawer will be placed at the top of the highlighted opening and the remaining opening will be left at the bottom. If you select *Adjust Top*, the drawer is

placed at the bottom of the highlighted opening and the remaining opening is left at the top.

You can, at any time, add multiple drawers of equal height to an opening but this will fill the entire opening. You cannot leave a gap when installing multiple drawers.

Now, simply press *OK*.

Once drawer boxes have been added, they can be deleted by highlighting them (left click to highlight, *Ctrl* and left click to highlight more than one) and pressing *Delete* on the keyboard or clicking the *Delete* icon on the top toolbar.

Note that you can inset the front of a stack of drawers and then add a door into the opening in front of the drawers in the *Door/Drawer Editor*.

## ***Working with Stretchers, Nailers, Braces and Other Internal***

### **Working with Stretchers, Nailers, Braces and Other Internal Parts**

There are a lot of different internal components used in cabinets including nailers, stretchers, webs, supports and sleepers among others. For purposes of this discussion we will call all of these “stretchers” regardless of their ultimate purpose.

Within the software stretchers are made from sheet stock and are nested along with other components made from the same material. You can make these from a board stock material by creating a new “sheet” material that is actually a board and specifying the size as 12” x 96” for example. Then when you actually produce the job you must remember that this particular material is a board stock even though the software treats it like sheet stock.

Stretchers can be positioned in a base or upper cabinet horizontally from side to side, vertically from top to deck or horizontally from front to back. A stretcher can also connect to any other fixed cabinet part such as fixed shelves, partitions or other stretchers.

For corner cabinets, stretchers are limited to nailers located against the cabinet back or sleepers located under the deck.

Stretchers can be given any joint construction with parts it contacts.

Stretchers are added to a cabinet in an area called *Stretcher Editor* accessed from the top toolbar.

*Left-Right*, *Up-down* and *Front-Back* stretchers can be placed in base and upper cabinets. Nailers and sleepers placed on corner cabinets are covered in a separate section of this manual.

For non-corner cabinets we start by defining the two cabinet parts that the stretcher spans between. Then we move, adjust and define how the stretcher acts as the cabinet size changes.

The way stretchers are initially added is defined by the *Add Stretcher Settings* area in *Construction Settings*. Let's start by examining these settings.

The first parameter is the *Width*. When combined with the *Material* which defines the thickness, we have the physical dimensions of the stretcher. As you will see, this width dimension is not all that important because the parametric nature of the *Stretcher Editor* makes it quite easy to adjust this

after it has been placed. If you know the exact width, no reason not to put it here and save some time later.

In the *Construction* area you specify the type of joint between the stretcher and other components. This is an important feature.

As long as the stretcher is perpendicular to and not positioned at an angle with another component and is against that component, it can be directed to make any available joint with that component. Therefore, a stretcher can have any joint with any cabinet component it contacts. It can also have a defined joint with any other stretcher it contacts. This is a powerful feature although it can be confusing until you get used to it.

The joints specified in *Construction Settings* refer to directions as seen from the cabinet itself. Therefore, if you set *Top* to *Blind Dado*, a horizontal stretcher whose top edge contacts the cabinet top is given a blind dado along that edge. Another stretcher that is positioned vertically from the top to the deck will find the top end has a blind dado joint.

This is an area you need to play with awhile to become comfortable.

The third area defines initial orientation of the stretcher. Each time a stretcher is placed between two components, it can have either of two orientations. For example, a stretcher placed between the left and right ends of the cabinet can be oriented *Front-Back* like a shelf or it can be oriented *Up-Down* like the cabinet back.

For purposes of these definitions, we define three types of stretchers, *Left-Right Stretchers*, *Up-Down Stretchers* and *Front-Back Stretchers*. Each can then be initially oriented in either of two directions. You can later rotate them to any angle if you want but initially they are one way or the other.

*Grain Direction* works like other components and *Construction Parameters* define geometric characteristics of the various joints.

Now let's focus on the *Stretcher Editor* and see how a stretcher is added and adjusted. We will use an example to show how this area functions. Let's add a stretcher from the left to the right side of a cabinet.

In the *cabinet/Assembly Editor* we have loaded the *Std. Base Frameless*. Click on the *Stretcher Editor* icon to open the *Stretcher Editor*. You have all the standard grid settings and display options available by right clicking and selecting *Grid Settings*. We will now designate the two parts that we want the stretcher between, in this case the left and right ends.

We will highlight the left end first, then the right end by clicking on each. The first part you highlight is the "control" part and will be used to adjust and refine the stretcher. Now press *Add Stretcher*.

You are now presented with the *Add Stretcher Settings* from *Construction Settings* which you are free to modify as needed. Press *OK* and you now have a stretcher in the center of the end panel. This is likely not exactly where you want it so we will adjust the stretcher.

Click on the stretcher to highlight it and press *Adjust Stretcher*. You are presented with the screen shown. Let's look at this information carefully because understanding it is key to positioning and defining stretchers.

The display in the center can be rotated, moved and zoomed like most other images. Sometimes

you need to rotate and move the image to see certain *Insets*. Also, if the part becomes too complex, you can turn off the display of certain *Insets* by unchecking the *Show* box across from it.

The area to the left controls the display, insets and locks and understanding the relationships between these is vital to understanding how to adjust stretchers. This can get somewhat involved at first but is fairly simple once you understand it.

Let's start by leaving the *Locks* off and adjusting the *Insets*. Basically the *Insets* define the distance from the stretcher to the boundaries of the part. *Insets 1,2,3* and *4* are the distances from the stretcher to the edges of the left end as shown. *Inset 5* is the distance from the end of the stretcher to the surface of the left

cabinet end, in this case zero. *Inset 6* is the distance from the other end of the stretcher to the surface of the right cabinet end (which isn't shown here). Again the distance is zero. The stretcher spans from the right end to the left end.

With all *Locks* off, should we change an *Inset*, *Inset 1* for example, to 5 inches, when we press *Enter* the stretcher will move up until it is 5 inches from the top edge as shown. Notice in this case that *Inset 2* has also changed. With *Locks* off, changing any inset moves the stretcher and also changes the opposite *Inset*.

Now let's go back to our original position (*Inset 1* at 16.25" and *Lock Inset 2* by placing a check in the checkbox. Then change *Inset 1* to 5 inches and press *Enter*. Now, the only way to make *Inset 2* - 16.25" and *Inset 1* - 5" is for the width of the stretcher to grow so that is what it did.

This demonstrates a key point in defining stretchers. The system will maintain the width of a stretcher unless the only way to satisfy *Insets* is to change the width of the stretcher, in which case it will change that width.

*Locked Insets* also help define what happens to the position of a stretcher as the cabinet size changes. Let's say we have a nailer (stretcher) at the very top of the back (*Inset 1* = 0"). If we want that nailer to remain at the top even if the height of the cabinet changes, we should *Lock Inset 1*. If we then leave *Inset 2* unlocked, the width of the stretcher will stay the same and it will always be located at the very top of the cabinet back.

In this case we would also want to lock *Inset 4* to keep the nailer properly positioned against the back even with changes in cabinet depth.

This same idea works for the length of the stretcher. *Inset 5* and *Inset 6* are both zero which means the stretcher just touches to cabinet ends. If we want the stretcher to remain exactly between the cabinet ends as the cabinet width changes we must *Lock* both *Inset 5* and *Inset 6*.

This does not, however, work with the thickness of the stretcher. The system assumes that the stretcher is made from a specific material which has a fixed thickness. In this case, if we were to *Lock Inset 3*, *Inset 4* is grayed out and cannot be changed.

The stretcher can also be rotated using the slide bar or designating the angle in the box. Remember, as soon as the stretcher is rotated, joinery between non perpendicular parts is lost. Also, once the stretcher is rotated, the image of the stretcher itself disappears and is replaced by the image of the bounding box. The bounding box is the smallest horizontal/vertical box that completely contains the rotated stretcher. *Insets* are measured from this bounding box for a rotated stretcher.

Press *Done* when complete, then return to the Main page by clicking the *Main* icon.

At this point, you can change construction (joinery) for the stretcher by right clicking on the stretcher and selecting *Construction*, then selecting the side you want to change and the joint you want.

## Adding Nailers and Sleepers to Corner Cabinets

For purposes of this manual, nailers, which mount against the back and sleepers, which support under the deck are both treated as stretchers. Nailers (stretchers) are always located against the back of the cabinet. When a corner cabinet is taken to the *Stretcher Editor* these are the only two elements that can be added.

Before working with corner cabinets, you should become familiar with using the *Stretcher Editor* to add stretchers to non-corner cabinets. This is covered in the section titled *Working with Stretchers and Internal Braces*.

We will again use an example to demonstrate these functions. Load the *Std. Corner Frameless* into the *Cabinet/Assembly Editor*. If it is not the only cabinet in the workspace you need to highlight it, otherwise just press the *Stretcher Editor* icon on the top toolbar.

We will first demonstrate how to add nailers.

Click on one of the back panels to highlight it then press the *Add Stretcher* button.

An abbreviated version of the *Add New Stretcher* dialog appears which you can modify if necessary. Since only back nailers can be added to corner cabinets, some of the fields are not needed.

When your parameters are correct press *OK*.

The stretcher has been added to the back of the cabinet to be used as a nailer. To adjust its position, click on it to highlight it and press *Adjust Stretcher*. A diagram and *Insets* similar to those discussed in *Working with Stretchers and Internal Braces* is displayed.

*Insets* and *Locks* work in the same manner as discussed in that section.

To add a sleeper under the deck, rotate the cabinet so that the under deck area is visible and highlight the parallel back panel and toe kick panel that you want the sleeper to span as shown to the left. Note that the first part you highlight in this process will be used when you want to

adjust the stretcher.

Press *Add Stretcher* and the *Add New Stretcher* dialog is displayed. Here you may want to adjust the *Width* to correspond to the distance from the bottom of the deck to the floor.

Press *OK* and a stretcher is added between the two highlighted parts as shown to the right.

To adjust the position, click on the stretcher to highlight it and press *Adjust Stretcher*. It is displayed along with the first part you highlighted

## ***Combining Cabinets and Assemblies in a Job***

The *Cabinet Assembly Editor* is used to modify and save cabinet designs. While working in the *Cabinet Assembly Editor* you can generate certain reports (*Cut List*, *Buy List* and *Cost Sheet*) for one or more cabinets or assemblies that are loaded in the workspace. You can also generate a CNC output file and send it directly to a Thermwood CNC router where the parts can be machined.

If you want to create nest diagrams, part drawings or part labels, if you want to actually purchase items needed for the cabinets or if you want to combine multiple cabinets and assemblies and then run reports, you need to establish a Job.

There are four things you do that will automatically establish a Job.

1. The first is *Batch Input*. In *Batch Input*, you simply add cabinets and assemblies to the Job. The Job is automatically established when you place your first item in the batch. At this point you can run reports for the entire Job, generate a CNC output file for the entire Job, run nest diagrams, part drawings and part labels and all purchased items needed for the Job are added to your *Shopping Cart*.
2. The second way to establish a Job in the software is through *Custom Layout*. In the *Custom Layout* area, you create walls that define one or more rooms, detail those walls, install cabinets and assemblies and create a three-dimensional representation of the finished job installed in the customer's location. This area also offers tools that allow you to generate rich, photo-realistic images of the final installation. These can be a great help in selling the Job.

A Job is automatically established when you begin creating your first wall in *Custom Layout*. Once cabinets are installed, you can run reports for the entire job.

As a note, if you have cabinets installed in a *Custom Layout* and also have cabinets that have been put into the Job through *Batch Input*, the reports and manufacturing output is for the COMBINATION of both areas. All cabinets and assemblies are included from both *Batch Input* and *Custom Layout*.

3. If you begin making a drawing in the *Drawing Editor* a Job is also established.
4. Finally, if you place items in the *Shopping Cart* you establish a Job.

Once a Job has been created, it can be saved under a Job name. It can then be reloaded and modified if necessary. This Job will have an .esj file extension. Therefore, when you do any of these four things, you can save your work as a Job.

## ***Using the Part Editor***

The *Part Editor* is used to modify any part of a cabinet or a *Display Panel*, *Display Board* or *Display Cube*. Not only can you modify these parts, but for parts made from sheet stock or for profiled edges, the modification is automatically added to the nest diagram and the required CNC program to machine the modified part is generated through the CNC feature. The part is modified by cutting through, pocketing or profiling it.

Modifying a part is typically a two step process. First, geometry is created on the surface of the part and then that geometry is used to cut, pocket or guide a profile tool. It is also possible to use the edge of a part to guide a profile tool but geometry must exist for a through cut or pocket cut.

There are two different ways to create geometry. Simple geometric shapes such as a rectangle, circle and filled arc can be defined and placed on the surface in the *Main* workspace. Several geometric shapes can be placed on the surface at once and the shapes can overlap. These shapes can then be highlighted and used to cut through, pocket or make a part from.

These simple geometric shapes can be modified, even after they have been cut by using the *Constraint Manager*. For example, to create a pattern of four holes, you could carefully create correct geometry and then use it to cut the hole pattern. You could also draw and cut four random circles, which can be done rather quickly, and then set their position and diameter in the *Constraint Manager*. See the section “Constraint Management for Parts Modified in the Part Editor” for more information.

External corners and, once cut, inside corners can be modified by filleting or chamfering.

More complex shapes are created in a separate area called *Contour*. This area is more CAD like and allows the development of more complex shapes and paths. The *Contour* area either creates open paths to guide a profile tool or it creates a closed shape that can be used to cut through or pocket.

The *Contour* area can also import two dimensional DXF files to help define the contour. This allows you to use most popular CAD systems to create geometry for parts or cut-outs and then bring those shapes into the software.

Before we demonstrate actual pieces, let’s take an overview look at the *Part Editor*.

This area is actually quite simple to use but very powerful. It is essentially a simple CAD system that operates on parts imported from the *Cabinet/Assembly Editor*.

Start by highlighting a part in the *Cabinet/Assembly Editor* and pressing the *Part Editor* icon. The part can be a single part of a cabinet or assembly or can be a *Display Panel*, *Display Board* or *Display Cube*. This opens the *Part Editor* with the part in the work area. The part is oriented flat and can be worked on from either side.

A part is selected in the *Cabinet/Assembly Editor* by SINGLE clicking on it. It then displays with a cross hatched highlight.

In the *Part Editor*, text depicting the orientation of the part helps provide orientation. The view can be changed from front to back or side to side by changing the *C-Plane* located in a control box on the taskbar just above the center of the workspace. There is also an X, Y position readout of the cursor position located next to the *C-Plane* control.

Although we refer to the *Part Editor* as a CAD system, it functions a bit differently than a typical CAD system.

In most CAD systems you draw lines and surfaces to define the exterior of a part. Then, if you want to actually make the part, you must define tools and tool paths that will cut the part from a blank. Finally, the size of the required blank is determined.

In the *Part Editor*, we start with a blank or a basic part and then use defined tools to cut away material to produce the desired final shape. In doing this we are automatically defining the required tools and the cutting processes needed to make the part. This approach makes it possible to quickly and easily machine any part developed in the *Part Editor*.

The *Part Editor* basically modifies the part in two ways. The first method uses geometry placed on the surface of the part. The geometry is created by either using one of the geometry tools such as the *Rectangle*, *Circle* or *Filled Arc* or by creating a closed geometric shape using the *Contour Mode*. This geometry is then selected and the part cut.

The part can be cut in two ways;

- It can be cut all the way through the part, creating a hole or cut-out the same shape as the geometry. It can also be cut only part of the way through the part, creating a pocket the same shape as the geometry.
- The geometry can be the actual part, cutting away all material outside the closed shape.

The second basic function of the *Part Editor* is to cut a profile on the edge of the part or along a contour on the part.

To cut a profile, a *Tool* is required that has the profile you want. This *Tool* is created in the *Shape Manager* and saved as a .tol file.

To demonstrate these features, let's start with a simple cabinet box and modify it to have a curved front, profile top and speaker hole.

Open the *Cabinet/Assembly Editor* and load the *Std. Base Frameless* from the *Standard Cabinet* directory.

We will start by creating the curved top and front. You should perform all function on the cabinet that will require changes in size, joint construction or overlap before modifying parts in the *Part Editor*. Once parts have been modified, no changes can be made to the cabinet that would require the size of the modified part to change. Should this happen, you will lose all modifications made in the *Part Editor* since the system does not know how to handle these changes as part size changes.

To prepare for the machining, we need to modify the top of our cabinet.

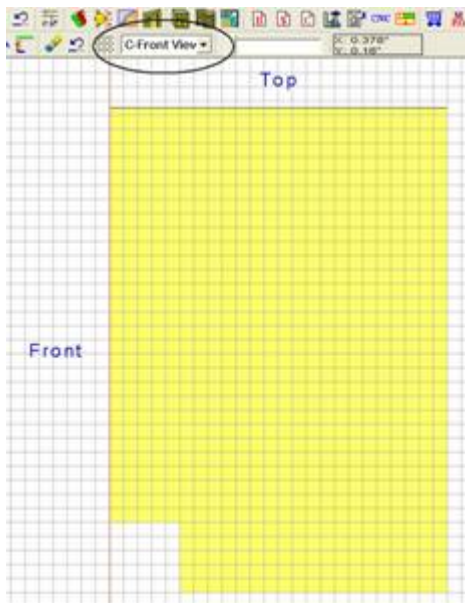

From the *Main* page of the *Cabinet/Assembly Editor*, right click on the cabinet top and select *Construction Settings*. This opens the *Construction Settings* area on the page that defines the *Top*.

Change *Placement* to *Top Flush*.

Set the *Front Inset* to a -4", *Right Inset* and *Left Inset* both to -1". Press *OK*.

The top now overhangs the cabinet box. We will return to the top later, but first we will place a speaker hole in the left side.

Highlight the left end by single clicking on it.

Notice that the highlight is a grid pattern on the entire part. This indicates that the individual part is selected. When a cabinet is selected, only the outline of the parts is highlighted. This distinction is important when working with cabinets and individual parts.

Then, click the *Part Editor* icon.

The part is displayed in the workspace as shown.

Notice the position of the “Top” and “Front” of the part is denoted. From this position information and the knowledge that this is the left end of the

cabinet, we can determine that we are facing the surface of the part that is inside the cabinet.

We would like to machine from the outside of the cabinet, so we must change the *View*.

Change the *C-Front View* in the control box circled to *C-Back View*.

Now you will notice that the “Top” and “Back” are shown and that we are looking at the outside surface of the part.

We are going to want to cut a ¼ inch deep square pocket into the side to hold a speaker cover and then cut a circle all the way through the part.

We will start by defining the geometry of the square and circle.

Select the *Rectangle Tool* icon to enter the *Rectangle* mode. Note that instructions at the bottom ask you to “Enter the first point X,Y”. At this point you can either position the cursor over the first point and click or you can enter the point manually in the box. If you want to use the cursor, it is almost mandatory that you set the *Snap Increment* and turn *Snap* on. Otherwise it is difficult to achieve a precise position.

We will use manual input. Type “6.5,11.5” and press *Enter*. Positions are entered in absolute coordinates with the X Axis position entered first, followed by a comma and the Y Axis position. The origin or 0,0 point is located at the bottom left corner of the part.

Next, type the end point, “17.5, 22.5” and press *Enter*. The rectangle is shown in gray.

We will now use this geometry to cut the ¼” deep pocket.

Click on the *Select Mode* icon from the toolbar. Then click on the rectangle we just created to highlight it.

From the *Right Click Menu*, select *Cut Shape*. In the dialog box that appears, put .25” in the *Specify Cutting Depth* field and press *OK*.

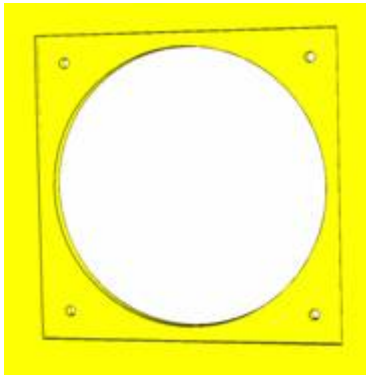

We can now examine the pocket by selecting the *Review Mode* icon. In this mode, the part can be rotated and zoomed using the normal controls used for cabinets.

We will now locate a circle over the top of the rectangle. Select the *Circle Mode* icon to enter the *Circle Mode*.

A circle is defined by specifying the location of the center and the diameter. Specify the center by typing “12,17” and pressing *Enter*. Input 10” as the diameter.

Switch to the *Select Mode*, highlight the circle and from the *Right Click Menu* select *Cut Shape*. This time select *Cut Through* and press *OK*.

We will next create geometry for the mounting holes in each corner. From the *Circle Mode*, create four circles each .375” in diameter with centers of:

7.5,12.5  
7.5,21.5  
16.5,12.5  
16.5,21.5

Next, switch to the *Select Mode* and click on each to highlight them. Again select *Cut Shape* from the *Right Click Menu* and cut them through.

We could also have placed the large circle and all four small circles and then cut them all through at the same time. We could have even placed all the geometry on the part first and then selected entities one at a time and cut them. This approach, however, can cause confusion because more than one entity is selected if they overlap at the point you use to select.

Placing all the geometry at once does have the advantage that certain nodes are available for *Object Snap*, such as the center of a circle or the corners and center of a rectangle. This can make location of geometry easier.

Press *Return* to return to the *Cabinet/Assembly Editor* and take the changed part with you.

The result on the cabinet is shown to the left.

We modified the left end by using the geometry tools.

Next, we will modify the top using the *Contour Mode* to create a closed geometric shape that cannot be developed using the simple geometry tools.

Highlight the top by single clicking on it. Now click on the *Part Editor* icon.

The *Front* is toward the left and the *Left* side is toward the top of the display. This means that we are looking at the top surface of the top, which is what we want. If this was incorrect, we could use the *C-Plane* control to change the view.

We want to put an arc across the front of the cabinet. To do this we need a closed arc geometry with a concave arc. The *Arc* mode available from the toolbar is a convex arc so we need to use the *Contour* mode to create the geometry.

Press the *Contour Mode* icon.

We will use the *Snap* functions to create the geometry. Press the *Grid Settings* icon and set the *Grid* and *Snap* each to 1" and make sure they are turned on. The *Dotted* grid display is probably the easiest for this application.

Place the cursor at the top left corner of the part. Notice that the cursor position is 0",32". This dimension will be needed shortly.

Select the *Circle/Arc Mode* icon, then select *Three Point Arc*.

Move 3" to the right to 3",32" and place the first point.

Now move to the left edge and down to 0",16". The 16" is half the 32" dimension we noted earlier. Place the second point.

Finally, move to 3",0" and set the last point. You now have the arc we need.

We must now turn this into a closed geometry so we can use the *Cut/Pocket Using Closed Contour* function.

Switch to the *Line Mode* and freehand some lines to close the shape. Their actual position is not important since only the arc will actually be used to cut the part.

Create lines as shown to we can use to cut the front

Now, exit the *Contour Contour Mode* icon from

We now want to cut this Geometry created using rectangle, etc.) use the *Contour* function to cut. geometry tools use a

*Using Geometric Shapes* to perform the same function.

develop a closed geometry that arc.

*Mode* by selecting the *Exit* the toolbar.

shape through the part. the geometry tools (circle, *Cut/Pocket Using Closed* Geometry created with the function called *Cut/Pocket*

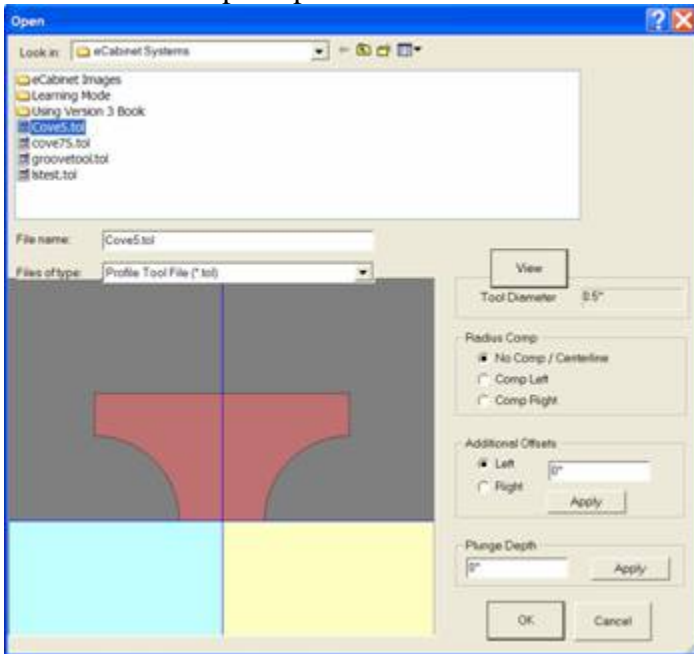

The system will try to help you determine which function to use based on your operation.; If you have placed geometry and have highlighted it, it will only offer the *Cut/Pocket Using Geometric Shapes* and the *Cut/Pocket Using Closed Contour* will be grayed out. If you have a defined closed contour and no geometry is highlighted it will offer *Cut/Pocket Using Closed Contour* and will gray out the *Cut/Pocket Using Geometric Shapes* option.

Now back to our part. From the *Right Click Menu*, select *Extrude Cut*. Then, click on any of the lines in the contour.

The entire closed contour highlights.

Now press *Done* to access the cut dialog. Check *Cut Through* and press *OK*. The part is cut as shown to the right.

We now want to put a profile on the front and the left and right edges of the part.

Select the *Profile Part* icon.

Since we are not going to go all the way around the edge but will cut more than one edge, we need to select *Partial* at the bottom of the display.

The guide at the bottom tells us to “select the first entity”. Click on the bottom (cabinet right) edge. Click near the back which is the right hand side of this edge. The direction around the part that the partial chain will take is determined by the location that you select. If you select the right side of the bottom edge as the

starting point, the profile will move away from the corner closest to the point you selected, in this case it will move counterclockwise around the part. If you select the left side of the edge as the starting point, the profile would move to the right and counterclockwise around the part.

At the bottom left starting point you will see the symbol shown. The red line with the dot indicates the starting point of the cut and the direction. The red dot is in the direction of the cut.

Then we need to “Select the last entity” which is the top (cabinet left) edge.

Now press *Next* to indicate you are finished with the path selection.

Using the dialog, find the path and file name where you saved the profile “Cove5.tol” and select it.

Press *View* to see the tool profile.

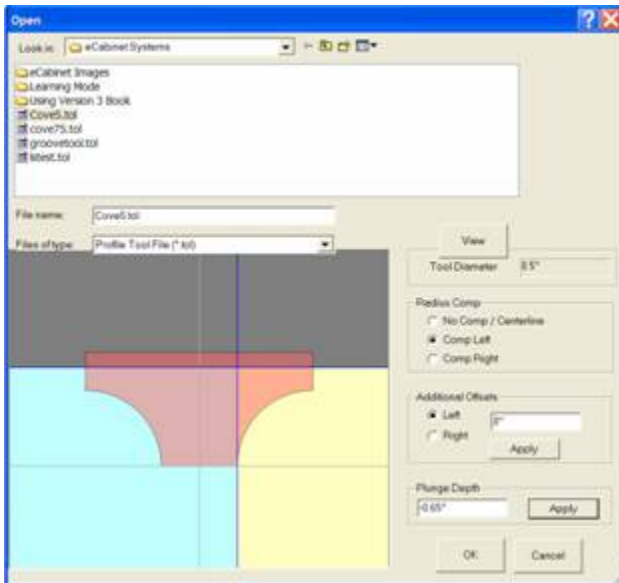

The blue and yellow areas beneath the tool signify the part. We must now set parameters that define how the tool cuts the part.

If you select *No Comp/Centerline*, the center of the tool will cut along the path.

If you select *Comp Left*, the tool shifts to the left and the part is represented by the yellow area on the right.

If you select *Comp Right*, the tool shifts to the right and the part is represented by the blue area to the left.

Next, input the plunge depth and press *Apply*.

Note that movement downward and into the part is the negative direction and movement upward and away from the part is the positive direction.

The image to the right shows our tool with *Left Compensation* and plunged - .625” into the part. Our part is represented by the yellow area.

The left or right designation for cutter compensation is determined by standing behind the cutter bit and watching it cut away from you. The direction to the left is left compensation and the direction to the right is right compensation.

The *Additional Offset* area allows you to offset the tool, left or right, in addition to the offset that occurs from tool radius compensation.

The actual offset caused by tool radius compensation may change at the machine if the diameter of the tool changes. If the machine operator indicates that the diameter of the tool has changed, due to sharpening for example, the system will automatically shift the

tool to compensate for the new diameter. This insures that the final part is the correct size.

At this point it is simply a matter of pressing *OK*.

You now see the part with the profile cut along the edges.

Now press *Return* and indicate you want to take the changes with you.

The result is the cabinet shown to the right.

The basic techniques shown here will work for sheet material, either a cabinet component or a *Display Panel*.

Using a *Display Panel* for a part rather than an actual part of the cabinet has some advantages. When you use an editor, such as the *Shelf/Partition Editor* or the *Face Frame Editor*, the entire geometry of the cabinet regenerate as you leave to incorporate the change you made. This regeneration may resize parts as part of the process.

The system cannot resize a part that has been modified by the *Part Editor* so, if the cabinet regenerates, you lose any modifications you made to any part of the cabinet. There is a warning about this if you try to enter an Editor with modified parts.

This can be avoided by waiting until all adjustments that require editors have been completed and then using the *Part Editor* to modify parts of the cabinet. A second choice is to make a *Display Panel* the same size as the cabinet part and replace the cabinet part with it. Then you can modify it without the danger of losing the modifications.

This *Display Panel* will not resize, however, you can regenerate the cabinet without affecting the *Display Panel*. If the changes you make to the cabinet requires that the part actually change dimensions, you will need to create a new part of the correct size.

We will next demonstrate some other techniques that can be used to develop different types of parts.

As an example, we will develop a curved door. This same approach can be used with a large *Display Cube* to create a curved wall for a room.

To do this we will start with a *New* screen in the *Cabinet/Assembly Editor*.

Next, load a *Display Cube* 4" Wide, 12" long and 30" Deep. Give it a wood texture you like.

Then click on it to highlight it and press the *Part Editor* icon.

We will use the *Contour Mode* to create a closed shape we can use to make the cut.

Press the *Contour Mode* icon to enter the *Contour Mode*.

Use the *Three Point Arc* and *Line* tools to develop a shape as shown to the left. Make sure you used the *Fillet* (with zero diameter) or *Trim* tools to be sure you have a closed contour.

Exit the *Contour Mode*.

Right click and select *Create Part Using Closed Contour*.

The result is shown at the right.

Press *Return* and keep the changes.

Here is our door. It has the correct shape but doesn't look very good. The grain texture is warped and does not look realistic. This is the result of how grain is mapped to parts in the *Cabinet/Assembly Editor*.

We will fix this by converting our part into a *Display Object* using the *Display Part Editor*.

We will *Export* the part as an HSF, then load it into the *Display Part Editor*, adjust the grain and appearance and save it. We can then load it back into the *Cabinet/Assembly Editor* as a *Display Object*.

resulting

Highlight the door by clicking on it.

Then from the *File* menu at the top left, select *Export Selection*. This will export whatever is highlighted as an HSF file. Give it a name and directory.

We can now go to the *Display Part Editor*, load the file and adjust the grain appearance and then save it again. Now its appearance is quite acceptable.

This technique adds a powerful capability to the system. For example, if you wanted glass shelves in a cabinet, you could highlight the shelves, *Export* them, change them to glass appearance in the *Display Part Editor*. Then you could load the *Display Object* back into the *Cabinet/Assembly Editor* and

locate the new glass shelves.

We will now develop a corner post for a cabinet with a V notched out where it meets the cabinet.

Return to the *Cabinet/Assembly Editor* and press the icon for *New* and say *Yes* you do want a new page.

We started in the *Shape Manager* where we created the shape of the leg we want as shown to the left. This was then made into a tool and saved. See the chapter on the *Shape Manager* for details on how this is done.

Next, in the *Cabinet/Assembly Editor*, create a *Display Cube 3" W x 3" H x 24" D*.

Highlight the part and press the *Part Editor* icon.

Once in the *Part Editor*, we will cut the corner notch first.

Use the *Rectangle* tool to place a rectangle that extends from the center of our block to the edge as shown. Highlight the rectangle, right click and select *Cut/Pocket Using Geometric Shapes*. Select *Cut Through* and press *OK*.

Now, press the *Fillet* icon and set the *Fillet Radius* to 1.5". Be sure to press *Enter* to make the dimension active.

Apply the fillet to the remaining three corners. The result is a round post with a corner notch as shown.

Next, we will apply the tool we developed for the leg to the outside of our part.

Press the *Define Cut Path* icon. Select *Partial* to indicate that we will not be cutting along a path that is closed.

Next, click on the lower right quadrant of our post to indicate that this is the starting segment of our partial chain. Then click on the upper left quadrant when asked for the end segment.

Press *Next* to move to the next step.

Select the tool you saved and press *OK*.

The shape of the tool is cut into the post.

Press *Return* and take the changes back to the *Cabinet/Assembly Editor*.

We can see the result to the left. It has the proper shape but again, we need to convert it to a *Display Object* to get a really good appearance.

Reset to the front view and highlight the part. From the *File* menu selection at the upper left, select *Export Selection*. Save the post as an HSF file.

Open the *Display Part Editor* and adjust the grain image. The most common adjustments are the *Texture Scale* and *Rotate*.

Then save the part as an HSF. This can now be loaded into the *Cabinet/Assembly Editor* or into the *Custom Layout*. Note that you can also *Export* from the *Custom Layout*.

The finished post shown to the right has been given a walnut grain which has been sized and rotated until the appearance shown was achieved.

As you can see from these exercises, the *Part Editor* is a powerful tool and allows you to produce almost anything.

The thing you don't see is that most of what you design can be machined using a Thermwood CNC router.

A really powerful feature is the ability to model a profile edge and then machine it without requiring a matching profile cutting tool.

The CNC router is able to do this by developing a modeling program from the data sent to it by the eCabinet Systems software. This is all done inside the Thermwood CNC control.

The modeling program starts with a ball nose cutter. It traces the path of the profile. Then it shifts over slightly and traces the path again. It goes back and forth along the path, shifting over a little each pass until the basic profile is generated. Then, if there are sharp inside corners that the ball nose tool couldn't reach, it uses a flat bottom tool to trace those. It can also use a pointed liner tool to cut sharp lines if required by the design.

This process is automatic and can be used to generate profiles on straight or curved parts. It can cut moldings like the one shown here. It can cut profiles on the edge of parts such as table tops or raised panels for doors.

The ability to model profiles is part of the initial release of Version 4 and the software you are using right now generates the CNC

files needed to do this. Additional capability is planned for future releases.

For example, in this guide we used a highly impractical 24” tall tool to generate turnings and posts. In future versions of the software, a turning capability is planned using the *Shape Manager* and *Part Editor*. This will make developing turnings easier but, the primary purpose is to automatically generate files needed to actually machine the turning on a Thermwood CNC router equipped with a rotary playback axis. The rotary playback axis is currently available as a machine option.

The current system can model virtually any molding or edge profile shape. In the near future you will also be able to create and then machine turnings quickly and easily.

### ***Importing DXF Files into the Part Editor***

Most CAD systems can export shapes, contours and part outlines in a file format called DXF. In many cases, part outlines or contour shapes are available in DXF format and it would be helpful to bring those shapes into the software. This is done in the *Contour Mode* of the *Part Editor*.

Once the DXF shape has been imported, if it is a closed contour it can be used to cut a pocket or through cut or a part can be made from the contour.

The DXF file is loaded using the *Load Geometry* icon at the upper left of the toolbar. When loaded, the origin or zero-zero point of the loaded file is placed at the lower left or zero-zero point of the part. The *Move* command can then be used to relocate the geometry if necessary.

Once loaded, the contour functions like any other contour that is developed in the *Contour Mode*.

### ***Adding Moldings to Cabinets***

There are three ways in the software to add moldings to a cabinet. The two primary methods are using the *Molding Editor* or adding the molding as a *Display Object*. Each has advantages and disadvantages.

The *Molding Editor* can add up to three horizontal moldings along the front and/or either side of the cabinet. By convention they are called *Top*, *Mid* and *Base Molding* but they can be located anywhere. The advantage of using the *Molding Editor* is that it automatically sizes the moldings to the cabinet and these sizes automatically change as the cabinet size changes. The disadvantage is that the moldings can only be positioned horizontally and there are provisions for only three moldings per cabinet.

The second way of adding moldings is by placing them as a *Display Object*. A function exists to make this relatively straightforward. The molding is then positioned relative to the cabinet, and it can be positioned in almost any orientation. The advantage of this approach is great flexibility but the disadvantage is that it is more involved, takes longer to do and the moldings do not resize or reposition with the cabinet.

Both of these approaches use a set of standard molding profiles which are also the profiles of moldings that can be purchased through the program. Some of the moldings supported are decorative or carved moldings that can create some interesting designs.

There is actually another way that can be used to create and place a custom molding but it is somewhat involved. In this approach you create a custom profile tool and then use that to cut the molding shape into a *Display Board* in the *Part Editor*. You then position this custom molding on the cabinet much like you do with a *Display Object* molding.

The advantage of this approach is that you can reproduce almost any molding profile. The disadvantage is that some of the tools used on *Display Moldings* such as the ability to miter the ends and resize it after it has been placed are not available for these custom moldings.

One interesting note on this approach is that if you have access to a Thermwood CNC router, you can actually make this custom molding without purchasing custom tooling. Thermwood machines include the ability to model pretty much any molding shape using some standard tools. This is a great feature, especially if you only need a limited amount of the molding.

Now let's examine the various approaches to moldings, starting with the *Molding Editor*.

The *Molding Editor* works like most other editors in that you set up the molding parameters in *Construction Settings* and then actually place the molding in the *Molding Editor*. You will notice that the area is called *Add Moldings Settings*. The "Add" again means that changes will not affect existing moldings, only new moldings we add.

You will also need to actually choose a molding to place at each of the three locations supported by the *Molding Editor*.

The *Molding Editor* only supports three moldings and there are settings for each of these three moldings in *Construction Settings* so this area does work a little differently than other areas such as *Add Shelf*.

In the *Molding Editor*, to change a molding it is not necessary to delete the existing molding and then add it back. Instead, you can simply change the parameters and then add then molding right over the existing molding. Whenever you add a molding in the *Molding Editor* you replace the existing molding with one based on the current molding parameters as defined in *Construction Settings*.

You will notice that for each molding you can specify if the molding is placed on the front and/or sides. You can also set a scribe on each side of each molding.

Each molding has a specific length that is considered “correct” for the current cabinet size. This “correct” length will make the molding exactly fit the cabinet with the corner joint selected. The *Scribe* number is used to vary that length. A quarter inch scribe will make that end of the molding a quarter inch longer than normal. For example, if you set an *Overlap* joint and set a quarter inch scribe, the molding will extend past the side by a quarter inch. If you set a negative quarter inch scribe the end of the molding will be shorter than the end by a quarter inch.

Once the scribe is set, the molding will remain a quarter inch longer than the end, even if the cabinet size changes. With a change in cabinet size, the molding also changes but always remains a quarter inch longer than the side it is mounted on because you have set a quarter inch scribe.

Once you have set the *Construction Settings*, the next step is to actually select the moldings you want. As you might expect, this is done by pressing the button *Select Molding*.

When you do, several vendors are presented. All except “Thermwood Furniture Network” have molding profiles that you can purchase through the program. There are also three-dimensional files that allow these to be displayed in the software. The “Thermwood Furniture Network” offers molding designs that are associated with a professionally designed furniture program that is discussed in another area of this manual. These designs can also be used in the software but are not available for sale. Instead, CNC programs to make them are available for rent. They can be run on a Thermwood CNC router so if you have one you can make these designs yourself. If not, you can generally find someone with a machine near you that can make them for you. A list of machine owners interested in machining parts for others can be found on the eCabinet Systems web site under *Production Sharing*”.

Click on a vendor and select a molding. Then you can set it as the “Default” molding for the top, middle or bottom. Note that on some moldings, you may have to move to the bottom of the window to access the red buttons.

It is also a good idea to add these to *My Favorites* to make it easier to locate them again should you need them. Now we are ready to actually add the moldings.

At this point, all we need do is locate the molding on the cabinet. There is a zero point on each molding. This point is normally at the bottom of the molding. At the upper left of the *Molding Editor* you will see two boxes titled *Distance to Top* and *Distance to Bottom*. These define a height on the cabinet and both boxes define the same point. You can use either to define the height point, but when you change one, the other also changes to reflect a single height on the cabinet. Two boxes are provided because sometimes it is

easier to measure from the top of the cabinet and at other times it is easier to measure from the bottom.

Once the height point is set, press *Add Top Molding*, *Add Mid Molding* or *Add Base Molding*. The default molding for the position chosen is added to the cabinet with its zero point located at the set point. If anything about the molding is incorrect, correct it, including the height, and then press the *Add* button again. You can keep doing this until you get what you want.

You might also notice that other than defining three moldings, the names *Top*, *Mid* and *Base* have no other function. Each of these moldings can be placed at any height on the cabinet.

You delete a molding by highlighting it and pressing the *Delete* button. The delete key on your keyboard or the delete icon can also be used. Notice that you highlight and delete each molding section separately even though all moldings of each type are added at the same time.

The major advantage of the *Molding Editor* is that moldings added using the *Molding Editor* will automatically resize and move as the cabinet resizes to maintain their position on the cabinet. The disadvantage is that all moldings are oriented horizontally and you can only add three moldings. The second method of adding moldings gets around these disadvantages at the cost of a bit more complexity and you give up the ability to automatically adjust for size changes.

For this second method we will return to the *Main* page of the *Cabinet/Assembly Editor*. Before you load the molding section, you might want to move the *Insert Target* to a convenient location because that is where the molding will be after it's loaded.

If you right click and select *Load Item*, you will see a selection called *Moldings*. Here again, you will need to select a vendor and a specific molding. Once again, both vendor moldings and Thermwood Furniture Network moldings are available for selection and once again you can buy the vendor moldings or make the furniture moldings.

At the bottom you specify the left and right miter as well as the length for the molding piece. The miter is specified in degrees. Note the difference between positive and negative miters. Press *OK*.

You are now back at the *Main* page and the molding has been loaded. You can now use the *Align* tool to position the molding. If you put a miter on the molding you will notice that the align nodes do not show up at the back of the miter. The align nodes occur at the corners of the item frame, an imaginary rectangular box that just contains the molding. These frames exist for every display item and you can make them visible by right clicking and selecting *Visibility – Show Item Frames*.

A fairly easy way to position the back of the miter on the molding is to use the *Align to Zero* feature and then press the *Align* icon again and shift the molding the depth of the miter cut, which for a 45 degree miter is also the width of the molding.

If you need to rotate the molding, single click on it to highlight it and then right click and select *Rotate Item*. An easy way to determine which direction the molding will rotate is to refer to the axis designator icon which shows the direction of each axis. You can then think of each axis as a pin or axel about which the molding rotates. Try this by moving each axis, one at a time and then returning to zero.

When you move more than one axis it gets a little more complex. Even in a new orientation, the part moves about the axis that existed before we started to rotate the part. Again, experiment with this to become familiar with the movements.

Once we have placed the molding, we commonly need to place additional sections of the same molding. Luckily, this is quite a bit easier.

We will simply copy and paste the existing molding using the standard Windows copy and paste commands. Highlight the molding and then press *Ctrl + C* to copy the molding to the system clipboard and then press *Ctrl + V* to paste it over the *Insert Target*. We now have an exact copy of the original molding.

At this point, a pop-up window should appear that lets you modify this molding. If it doesn't, highlight the molding, right click and select *Edit Molding*. Now check *Launch on Copy/Paste*. Now the window will pop up each time you copy and paste a molding.

Simply reset the parameters and locate the new molding. If you need another molding and you haven't copied anything since the last molding you only need to press *Ctrl + V*.

The moldings you add here will show up on either the *Cut List* or the *Buy List* depending on whether you need to make them or buy them.

Again, you can place any molding anywhere using this approach but they will not behave properly when the cabinet size changes. Also, remember, if there is more than one cabinet loaded in the workspace, you will need to highlight the cabinet you want the moldings associated with or specifically associate them with the cabinet before saving.

The only real disadvantage to the last two approaches to moldings is that you have a limited number of molding profiles to work with. There is a third approach to moldings that allows any profile but is somewhat more complex and does have some other limitations.

Using this approach, we will actually create our own molding using the *Part Editor* and then place it on the cabinet. This approach uses the *Shape Manager* to create a molding tool and then loads a *Display Board* that is the overall size of the final molding. This *Display Board* is then taken to the *Part Editor* and the molding profile cut into it.

You will want to refer to the section on the *Shape Manager* for detail description of the process of creating a tool, however, the tool we create for a molding is rather odd looking. This undercut tool essentially defines the molding profile although it could not be used as a router tool. In this case we are going to be modeling the molding rather than cutting it on a router or molder so it doesn't really matter.

A typical molding tool is shown to the right. You will notice that we did not make it symmetrical about the center axis. The entire tool was created in the positive X and Y quadrant of the workspace. This saves time but it also means that you need to apply the tool in the correct cutting direction. If you apply the tool starting

on one end of the molding and it doesn't work, try starting on the other side. Normally, you start the cut at the bottom left edge of the board in the *Part Editor*. Also, be sure to set the path to *Single*.

The molding can be taken back to the *Main* page of the *Cabinet Assembly Editor*, positioned and used.

At this time, it is not possible to cut a miter on the ends of the part for display in the software. From this, however, it is possible to model the molding shape on a Thermwood CNC router. This offers a great tool for making odd moldings in small quantity with relatively little effort at fairly low cost. This also offers a way to create display moldings for custom jobs provided you can work around the limitations with the miter.

## ***Adding Edge Banding to a Cabinet Part***

It is possible to apply edge banding material to one or more edges of cabinet parts. This applies to all the basic cabinet parts as well as partitions and shelves. Banding on slab doors and drawer fronts is defined in the *Door/Drawer Editor* when the slab door or drawer is defined. Banding for all other parts is defined in the *Edge Banding Editor* accessed from the top toolbar.

Before banding can be added, it must be defined. Edge banding material is defined in *Settings/Preferences – Define Stock Materials*. When added to a part, part size is reduced to allow for the thickness of the edge band and the edge band is shown in the cabinet display. This is more apparent if edge banding is a different texture than the rest of the cabinet.

You cannot place edge banding on any edge that has construction such as dado or blind dado. Also, for cabinet ends the toe kick notch is not banded. You also cannot place edge banding on any edge that is cut or modified in the *Part Editor*.

The total amount of edge banding needed is shown on the *Cut List* which also details each edge of each part that is banded. Part labels also show which edges of the part are edge banded.

Edge banding is applied in the *Edge Banding Editor* accessed from the top toolbar.

When the editor is first opened, you are offered a list of cabinet parts. Edge banding is defined one part at a time. Begin by selecting a part and then define the edge banding for that part. Note that for *Shelf* and *Partition* these are *Add* features which means that the edge banding selected here will not apply to existing shelves or partitions but will apply to any new shelves or partitions that are added. For all other parts, adding edge banding here automatically adds it to the existing cabinet part.

There are three components to banding a part,

- selecting the edge to band
- selecting the banding material
- defining the overlap with banding on connecting edges.

The edge to band is selected from the list at the top. *All* selects all edges for this part. Otherwise you must select a single edge to band. When this is complete, you can add banding to another edge. Basically, you can add banding to all edges or to one edge at a time.

This approach allows you to add different banding to each edge.

You can view the banding added to each edge in the *Edge Summary* display.

Banding material is selected from those available at the top of the dialog. If you select *None*, no banding is added to the edge. If banding currently exists, it is removed. Otherwise the banding selected is used on this edge.

Select the edge and the banding material and it is added to that edge.

Finally, you can define how the banding you are adding overlaps banding on connecting edges. In the *Overlap Preset* area, you can select from typical overlap patterns or you can custom define the overlap. If you select *Custom*, you are presented with a set of checkboxes where you can define the overlap.

When you have completed this part, press *OK* and you can select the next part for banding.

## ***Dealing with Face Frames***

Face frames can get a bit complex and the way the software handles face frames can be confusing at first. It was done this way to allow the maximum flexibility but it can also cause confusion when first learning the software.

The source of this confusion come from the fact that certain face frame components such as top and bottom rails and left and right stiles are controlled by parameters in *Construction Settings* and not controlled in the *Face Frame Editor*. These can be changed by going to *Construction Settings* and not even using the *Face Frame Editor*.

Other components such as mid-rails and mid-stiles are handled as “Add” type parameters. That is, unless they were highlighted before entering *Construction Settings*, existing mid-rails and mid-stiles do not change when these parameters are changed.

This is where the *Face Frame Editor* comes in because that is where face frame components are added and their position adjusted. These are primarily mid-stiles and mid-rails but top and bottom rails and left and right stiles can also be added should they have been deleted before.

As for positioning face frame components, the outside parts, top and bottom rails and left and right stiles are positioned with respect to the cabinet in *Construction Settings*. Only the positions of mid-rails and mid-stiles are adjusted in the *Face Frame Editor*.

It might be easier if you think of the *Face Frame Editor* as the *Mid-Rail/Stile Editor* and consider the outer frame as part of the cabinet just like the sides, deck and top.

We will start with the outer frame.

The outside frame consists of a top and bottom rail and a left and right stile. With respect to this outside frame the *Face Frame Editor* has only three functions. First, you can delete any of the frame components. Second, you can add a component back after you deleted it and finally, you can change the overlap. Normally, the stiles extend over the edges of the rails. You can change this in the *Face Frame Editor* by right clicking on the joint you want to change and selecting *Face Frame Options – Toggle Overlap*.

The rest of the changes to the outside frame are done in *Construction Settings*. It doesn't matter if *Construction Settings* is accessed from the *Main* page of the *Cabinet/Assembly Editor* or from the *Face Frame Editor*.

In *Construction Settings*, let's first look at settings for the entire face frame.

Under *Cabinet Attachment* you are given two choices, *Butt Joint* or *Blind Dado*. This specifies how the face frame attaches to cabinet box. Currently, only the butt joint is

supported even if you check *Blind Dado*. In the future, a blind dado will be available on the front edges of the cabinet to attach to a slot cut into the face frame, but not right now.

*Construction* determines how the face frame components attach to each other. The *Butt Joint* specifies the length of each component with no additional length for joinery and assumes some type of mechanical fastener such as pocket screws. If you select *Mortise Tennon*, then the *Depth* dimension is added to the length of any part on which a tennon is needed. This addition, however, is only done in the CNC output. Cut lists and part lengths only reflect the actual part to part dimensions that you would see with a butt joint.

The final common dimension for the face frame is the *Thickness* which is found on the second page of *Face Frame Settings*. Only thicknesses of existing board stock material are available for selection and once you select a thickness, only board stock with that thickness is available for selection as a material. The software assumes that all face frame components are the same thickness.

A convenient *Define Materials* button at the bottom takes you directly to the materials area of *Settings/Preferences* where you can add board stock material for your face frame. It is common to get here and need a different width material and this button saves some time.

On Page 2 you will notice a *Display Finish – Common with Door* checkbox. Normally this is checked and the face frame will take on the same color and texture as the doors selected. Face frame finish will also change when you change doors. If you want the face frame a different finish than the doors, uncheck this and the face frame will be the texture and finish assigned to the board stock the frame is made from.

We are now ready to look at the outside frame itself.

There are three things you can control for each component, its relative length, its position with respect to the cabinet and the material it is made from, which defines its width.

Let's start with its relative length. A face frame component is supposed to be a certain length. This length is defined by the width of the cabinet and the width of the parts it mates with, etc. and this length changes as the cabinet or other items change. By using a thing called an "*Inset*" you can make the component longer or shorter than its normal length. Since it's called "*Inset*" a positive number insets it or makes it shorter. A negative inset then, makes it longer. In a lot of these settings it is important to remember that you can use negative numbers and reverse the effect.

The position with respect to the cabinet is controlled by a parameter called "*Outside Scribe*" that is except for the bottom rail where this parameter is called "*Deck Float*". *Deck Float* is a little different as you will see.

*Outside Scribe* is essentially the distance the face frame extends past or outside the edge of the cabinet. For example, a quarter inch *Outside Scribe* for a top rail means that the top

edge of the top rail is a quarter inch above the top of the cabinet. The left and right stiles were also extended a quarter inch to keep the frame in tact.

Here again, we can use negative *Outside Scribes* to move the component toward the inside of the cabinet.

*Deck Float* is a bit different since it refers to the top edge of the bottom rail with respect to the top of the deck. If you set a quarter inch *Deck Float* the bottom rail will extend a quarter inch above the surface of the deck. Again, you can use negative numbers to lower the bottom rail.

Now let's look at the *Face Frame Editor* and the addition of mid-stiles and mid-rails.

The material and settings for mid-stiles and mid-rails are established in *Construction Settings*. Then, in the *Face Frame Editor* we add them and adjust their position.

This area works like the *Shelf Partition Editor* in that we highlight the area, add the part and adjust its position.

Simply click to highlight the open area. The highlight only looks at the face frame and ignores shelves and partitions inside the cabinet. Then pull the list down for the *Add* and click on the item you want to add. This is normally a mid-rail or mid-style.

If you want more than one and want them different from each other, add the first, go to *Construction Settings* and make the changes and then return to the *Face Frame Editor* and add the second one.

The mid-rail or mid-stile can be moved by clicking on it to highlight it and the while holding the *Shift* key moving it with the left mouse button. The only reason you might want to move it this way is to get it near a shelf or partition. If you get it near a shelf or partition you can then adjust its position by adjusting the float number. This float number will only appear if the rail is near the shelf or partition.

Another way to adjust the mid-rail is to highlight the opening above or below it. Then you can adjust the opening height in the box at the upper left.

Note that to the right of this adjustment box is a button under the word "Adjust" that changes from *Top* to *Bottom* to *Both*. This determines what part moves to obtain the height you set. With only one mid-rail, obviously if you highlight the top opening you can only adjust the bottom which is the mid-rail. In some cases, however, you may be adjusting openings between mid-rails and this feature becomes important.

This same thing works with mid-stiles, except you may be adjusting the width of the opening also.

Another important feature is the ability to highlight more than one opening and *Equalize* them. If you highlight two or more adjacent areas and press *Equalize*, the overall height of the combined highlighted areas remains the same but the mid rails or stiles are adjusted so that all openings are equal height.

To delete a face frame part, highlight it by clicking on it and either press the *Delete* button or press the *Delete* key. Note that you can highlight more than one part by holding the *Ctrl* key while clicking.

## ***Using the Shelf Partition Editor***

This area is used to add and adjust shelves and partitions. The process is simple, highlight the area where you want the shelf or partition, add it and adjust its position if necessary. As with most functions, the basic idea is simple, but there are a lot of details.

There are two types of shelves, fixed and adjustable. Fixed shelves are joined to the cabinet ends using one of the standard joints. Adjustable shelves are smaller than the opening and are generally supported by some type of shelf pin or clip. There is normally a series of holes drilled into the cabinet ends to hold these clips.

Partitions are only fixed and must mount into either a fixed shelf or a fixed part of the cabinet.

The software handles shelves as two different types, fixed and adjustable, and there is a set of parameters for each type. When you place a shelf, you specify if it is fixed or adjustable and the system uses the corresponding parameters.

The parameters are adjusted in *Construction Settings* under the tab *Add Shelf Settings* and a separate tab *Add Partition Settings*. As with any “*Add*” parameters, changes only affect items added after the change and do not affect any shelves or partitions that currently exist. You can highlight an existing shelf or partition and then make the change and the change will be applied to the highlighted item but otherwise, changes in “*Add*” settings do not affect existing items.

This is done so you can add different shelves each with different characteristics to the same cabinet. Set parameters for the first shelf and add it. Then change the parameters and add a second shelf. Each is different.

For fixed shelves, you can select the type of joint you want on the right, left and back. For adjustable shelves you can specify the left and right inset (clearance) and you can specify a hole pattern. If your cabinet will have more than one adjustable shelf, this hole pattern can get a bit tricky.

You must realize that the hole pattern is part of the shelf. When a shelf is added, the hole pattern is also added to the corresponding cabinet sides. If you move the shelf location up or down, the hole pattern moves up and down with it.

This is OK for the first shelf, but if you add another shelf you get another hole pattern. Add a third shelf and get yet another set of holes. We obviously need a little technique here.

Normally you want a single set of holes and then several shelves that can be mounted on any of the holes. To do this, specify the entire hole pattern for the first shelf. Also make sure if you relocate the shelf the hole pattern is properly located. Then, uncheck *Apply Shelf Holes* and add the remaining shelves. You should locate them so they correspond to the hole locations to make it more realistic.

Note that you can inset the front and back of a shelf and create a drawer stretcher. You can also inset either or both sides which can be useful when combined with partitions to develop boxes or freestanding shelves (for pocket doors) inside the cabinet.

Now let's place some shelves and partitions.

In the *Cabinet/Assembly Editor* load the *Std. Base Frameless*. Then click the *Shelf Partition Editor* icon.

Again, the process is simple. We highlight the area where we want the shelf or partition and then press the *Add Shelf* or *Add Partition* button. Be sure to select either *Fixed* or *Adjustable* for your shelf.

Once the shelf is in place we can move it up or down.

A quick way is to click on the shelf to highlight it and then holding the *Shift* key, use the left mouse button to move it. Although it is quick, it is not very precise.

You can read the height of the opening above and below the shelf in the display box at the upper left corner of the opening.

Another more useful way to adjust the shelf is to highlight the opening above or below the shelf. Then you can adjust the height of the opening at the upper left.

Note that to the right of this adjustment box is a button under the word "Adjust" that changes from *Top* to *Bottom* to *Both*. This determines what part moves to obtain the height you specify. With only one shelf, obviously if you highlight the top opening you can only adjust the bottom which is the shelf. In some cases, however, you may be adjusting openings between shelves and this feature becomes important.

This same thing works with partitions, except you may be adjusting the width of the opening also.

Another feature that can save you a little time is the ability to highlight more than one opening and add a shelf or partition to all of them at the same time. To highlight more than one opening, hold the *Ctrl* key as you click on each area.

Another useful feature that takes advantage of the ability to highlight more than one opening is called *Equalize*. If you highlight two or more adjacent areas and press *Equalize*, the overall height of the highlighted area remains the same but the shelves are adjusted so that all openings are the same. This also works for the width of partitions.

To delete a shelf or partition, highlight it by clicking on it and either press the *Delete* button or press the *Delete* key.

The final detail to cover is the *Insert Button Set*. In this area you can select whether the *Insert* key on your keyboard places a shelf or partition. Then you can use the keyboard *Insert* key instead of the on-screen button. Not sure how useful this is but it is there so feel free to use it.

## ***Moving and Aligning Items in the Workspace***

The *Cabinet/Assembly Editor* has powerful tools for moving, aligning and positioning items within the workspace. This is another area that can be confusing at first but is quite simple when you figure it out.

First, let's define what we are aligning. These features are used to align independent items, that is multiple cabinets, assemblies or parts that are not controlled by an Editor. You cannot use the *Align* feature to align cabinet parts with the cabinet they are part of. This must be done in the appropriate editor. For example, moldings that are placed as a display item are positioned using the *Align* tool described here. Moldings that are placed using the *Molding Editor* are positioned in the editor, not using the *Align* function. Just remember that items such as face frames, shelves or moldings added using the *Molding Editor* are aligned in their individual *Editor*. Cabinets, assemblies and other display items are aligned with each other using the techniques we are about to cover here.

The key to understanding is realizing there are two ways to move an item, you can move the entire workspace with the item in it. When you do this the item does move on your screen. You can also leave the workspace stationary and move just the item within the workspace. If there is more than one item in the workspace, only the item selected will move.

If you want to examine items in the workspace, you move, zoom and rotate the entire workspace. If you want to move items together or apart, you must move and rotate items within the workspace.

When you first enter the workspace, you are looking at a three dimensional workspace defined by three axes, X,Y and Z. The entire workspace is rotated by holding the *Shift* key and using the LEFT mouse button, it is panned using the *Shift* key and RIGHT mouse button and zoomed using *Shift* and BOTH mouse buttons. The key ingredient is that when you hold the *Shift* key you are moving the ENTIRE workspace and everything in it.

To move an item within the workspace, highlight it, hold the *Ctrl* key and use the RIGHT mouse button. Remember, *Shift* key to move the workspace, *Ctrl* key to move the item.

At this point, you need to deal with a feature called the *C-Plane*. When you first enter the *Cabinet/Assembly Editor*, you are looking directly at the *XY Plane* with the X Axis defining left and right movement, the Y Axis defining up and down and the Z Axis defining in and out. The *C-Plane* is also set to the XY Plane called *C-Plane Front*. This means left and right movement of the mouse moves items along the X Axis and up and down movement of the mouse moves items along the Y Axis, or mouse movements correspond to a front view.

Since you can rotate the entire workspace, you can orient the workspace so that these motions don't make sense. For example, if you rotate the workspace 90 degrees to the left, the mouse motions behave differently. Up and down motions still work because the Y axis is still pointed up. Side to side mouse motions still move the item along the X axis, but now the X axis is in and out, not side to side.

To get the mouse motions to correspond to the new workspace orientation we need to change the C-Plane. If you are looking at the left side of the cabinet, change to *C-Plane Left*, if you are looking at the right side of the cabinet change to *C-Plane Right* etc. Basically, this reassigns mouse motions to different axes so that the item moves on the screen as you feel it should, that is it move side to side when you move the mouse side to side and up and down when you move the mouse up and down. The C-Plane determines what the mouse does.

The *Reset View* feature sets the workspace orientation to the *Front, Left, Right, Back, Bottom* or *Top* and also automatically sets the appropriate C-Plane. You can also execute these using the arrow keys, left arrow for left view, right arrow for right view, etc. The *Home* key gets the front view and the *End* key the back view. This is probably the quickest way to change views once you get used to it.

Through this discussion we have been talking about moving left right, up and down. The third axis, in and out or zoom also exists (*Shift* and Both mouse keys). It exists throughout these movements and is also changed with changes in the C-Plane.

Now that we have looked at moving the workspace, let's look at moving items within the workspace.

We have already partially covered moving items within the workspace. Highlight the item, hold the *Ctrl* key and use the RIGHT mouse button. Unlike the workspace itself, an

item cannot be rotated in the workspace using the mouse. Instead, to rotate, the item is highlighted and you right click and then select *Rotate Item*. A dialog appears that can be used to rotate the highlighted item. Note that only one item can be rotated at a time. This is OK because it is difficult at best to try to accurately rotate an item using the mouse and when you are trying to align items, they must be precisely rotated. The dialog is a good way to do that.

You can align parts by carefully using the mouse but there is a better, faster way, the *Align* feature.

Start by rotating the items so that they are properly rotate with respect to each other.

Now, press and hold the “M” key on your keyboard. All those blue dots are called alignment nodes. They are used to align items with each other.

Release the M key and highlight the cabinet by double clicking on it. Slowly move your mouse cursor over the corners of the cabinet and the alignment nodes will appear.

We are going to pick a node on one item and then pick a node on a second item and then move them together. Make sure the two items you want to align are both highlighted and also make sure nothing else is highlighted. We will explain why in a minute.

In this move, one item will remain fixed and not move, and the other item will move to the first. The first item you click a node on remains fixed. This is important. The first item you click a node on remains fixed and doesn't move.

Move over a corner and when a blue node appears, click. The blue node now remains lit even when you move away. By the way, the blue color also indicates that this is the node that will not move.

When you move over a corner on the second part, a red node appears along with a line connecting it to the blue node. The red color indicates that this is the node that will move. Go ahead and click.

Now, the blue node, the red node and the connecting line are all lit meaning we are ready to do the alignment.

Click on the *Align* icon in the toolbar or right click and select *Align Items*. A dialog appears.

The dialog currently displays the X, Y and Z distances separating the two nodes. You can type in the distances you would like the nodes separated by after the move and press *OK*. If you want the nodes moved together with zero distance on all axes, simply press the *Align to Zero* button.

Once the move has occurred, you can move and rotate the workspace to see if that is what you wanted. If not, you can press the *Align* icon again, bring up the dialog, make adjustments and press *OK* again.

You can do this over and over until you select a new node or change focus by starting a new function.

There is another way to move a part a precise distance, but it uses the *Shift* key which is normally used to move the workspace. Despite this it can be quite useful.

Start by defining the increment by which you want to move. Right click and select *Edit Move Increment*. In the dialog input the distance and press *OK*. This is the incremental distance the item will move each time the key is pressed.

Now, highlight the item to move. If you hold the *Shift* key, the left, right, up and down arrow keys can be used to move the item. Note that the keys move along the axes that correspond to left-right up and down mouse movement and that they change with changes in the C-Plane. Although this may sound a little confusing, if you play around with it a little, it soon becomes second nature.

The next area is placing items such as carvings, hardware or other decorative items on a panel where convenient nodes don't necessarily exist. There are two considerations. First, we must align the back of the item to the face of the panel, then we must locate the item on the face.

There are two ways to align the back of the item to the face of the panel. First, you could align a node on the back of the item with a node on the face of the panel, even though the location isn't correct. Then switch to a front view and move the item into position on the panel using the mouse.

A second approach is to switch to the *Orthographic View* and a side view of the panel. Then using the mouse, align the back of the item with the front of the panel. Since we aren't using perspective, this is relatively easy to do. Then switch back to a front view of the panel and position the item using the mouse. You can then switch back to the *Isometric* view.

## ***Selecting and Associating Hardware to a Cabinet***

In addition to wood based material, there are other items including pulls, slides, hinges, catches, lazy susans, tip outs, slide outs and the like that may be needed to complete a cabinet. These items can be added to the cabinet providing several important benefits.

The first benefit is the ability to include the cost of these items in the cost estimate for the cabinet. Second, when multiple cabinets are added to a job, the software can add up all

the items you need for the entire job and provide these to you in a Buy List. Then, with little effort, everything on the list can be purchased through the program, saving considerable time.

For items that must be mounted to the cabinet, another benefit is the ability to automatically add the mounting holes to the appropriate cabinet parts. Hardware mounting hole patterns are included for most hinges and slides available through the program and the *Hardware Hole Editor* can modify these patterns or create new patterns if necessary.

Hole patterns are shown on individual part drawings and are included in CNC programs.

Finally, for many decorative pulls there is a rich three dimensional image that can be displayed on the cabinet providing an accurate representation of the final appearance.

There are two methods of handling hardware selection within the software.

First, there are default hardware selections for certain items such as hinges and hinge mounts for doors, slides and slide mounts for drawers, pulls for both doors and drawers as well as top, mid and base moldings for the cabinet. These are called “Cabinet Defaults”. Cabinet Defaults also include KD/RTA fittings for each joint when these are used.

There is an area where these selections are maintained. This area can be accessed either by selecting the *Define Default/Add Item* icon in the *Cabinet/Assembly Editor* and then selecting *Cabinet Defaults* or, from the *Door/Drawer Editor* you can press *Hardware Selection*.

Here you select the vendor and the actual item you want. You can also add them to *My Favorites* which makes finding them much easier in the future.

Default items for a door, hinges, hinge mounts and door pulls are automatically added to the cabinet whenever a door is added to the cabinet. Once you set the defaults, you do not need to worry about adding hardware when you add a door, it happens automatically.

This same thing works for drawers.

The second way of adding an item to a cabinet is using the “Add Item” feature. This allows you to select anything from the eCabinet Systems store and associate it with a cabinet. Whenever that cabinet is added to a job, the associated items are also added to the job.

This works well for items such as tip outs, roll outs or lazy susans. To position these properly, you need to know how to move and align parts in the workspace, so we will cover that next

## ***Constraint Management for Parts Modified in the Part Editor***

When you modify a part in the *Part Editor*, the modified configuration of the part remains valid as long as the part size does not change. When part size changes, there are normally multiple ways *Part Editor* modifications can react. The *Constraint Manager* allows you to define how you want the part modifications to act as the cabinet size changes.

In short, this means that the *Constraint Manager* tells the system what to do with *Part Editor* modifications as the underlying part size changes.

There are two things you need to understand in this area. First you need to know how the area works to constrain or control the part shape as its size changes and then you need to understand the default behavior should you not provide any constraints.

The *Constraint Manager* is accessed from the Main area of the *Cabinet/Assembly Editor* through an icon in the top toolbar. It loads an entire cabinet and then works with any modified parts on that cabinet, one at a time. You must highlight a cabinet by double clicking on it if there is more than one item loaded in the workspace. The cabinet must be highlighted before you enter the *Constraint Manager*.

An interesting feature of the *Constraint Manager* is that you can not only constrain certain dimensions but you can also *Edit* them. For example, if you cut a circular hole in a panel in the *Part Editor*, you can change both the diameter and the position of the hole in the *Constraint Manager*. In some cases, creating a hole pattern for example, it might be easier to just cut the initial holes in the *Part Editor* in random diameter and positions using simple mouse input and then specify the exact diameter and position in the *Constraint Manager*. This will become clearer as we examine how the area works.

When you first enter the *Constraint Manager*, the first part from the cabinet is loaded. The part name is shown in the display box at the center top. If more than one cabinet part has *Part Editor* operations, you can list and select other parts using this dialog box. You will define the constraints for every part of the cabinet that has *Part Editor* operations before leaving the area. These definitions remain with the cabinet when it is saved.

Operations can be constrained on both the front and back of the part. Those operations that were performed from the front side in the *Part Editor* are accessed from the front side in the *Constraint Manager*. Those operations that were performed from the back side in the *Part Editor* are accessed from the back side in the *Constraint Manager*. Switch between front operations and back operations by right clicking and selecting *Operations* and either *Front Ops* or *Back Ops*.

The *Constraint Manager* functions by fixing of “constraining” certain dimensions. Press the “M” key to see the constraint nodes that are available for selection.

We can constrain a node either horizontally or vertically. We can also constrain the diameter of a circle or arc. The best way to understand the operation of this area is to use some examples.

We will start with the cabinet side shown. It has a circle and a rectangle cut through it.

Let's start by seeing what happens when the depth of the cabinet increases. In this case, we will change the cabinet from 24" deep to 48" deep.

The *Constraint Manager* has a *Test* function that allows you to change the size of the cabinet and see the effect of the constraints you have defined. Press the *Test* button, input a new cabinet size and press *Enter*.

In this case, we have not defined a constraint, so the geometry maintains a proportional position with respect to the center of the part. If the geometry were located exactly in the center, it would stay in the center as the part size changed.

Let's assume, however, that we would like the circle to remain the same distance from the front of the part as the part size changed.

What we want to do is constrain the center of the circle to a fixed distance and measured horizontally.

Press the horizontal constraint icon in the top toolbar. Then move the cursor over the center of the circle until the center node displays. Click.

Next, move the cursor over the upper left corner of the part until the node appears (the lower left corner also works). Click.

Now you have a small box with an X in it. This indicates where the text defining the dimension will be placed. Move it to a convenient location and click.

This capability to locate the text is provided because on some complex parts, there are a lot of constraint dimensions and they can get confusing so this allows you to position them in the next possible location.

In this case, the center of the circle will remain 10.475" from the front of the cabinet.

Let's say, however, that that is not exactly what we want. We want the center of the circle 10" from the front.

Press *Edit*. Then click on the 10.475" dimension to highlight it. Then, input the new dimension (10") in the dialog box and press *Enter*.

The center of the circle is now located 10" from the front of the part. Lets double the depth of the cabinet and see the result of this new constraint.

As you can see, the circle stayed 10" from the front of the part as the part size doubled.

This same thing works vertically with the top or bottom of the part.

Before we move on, you should note that the location of the text for any constraint can be changed by pressing the *Move* icon and then clicking on the text you want to move. You can then move the text to a new location and click again to anchor it.

The only way to keep the part size changes is change and that is exactly what happens as seen to the right.

Now let's look at the bottom rectangle. In this case, we will constrain the left edge of the rectangle to the front of the part and the right edge of the rectangle to the back of the part.

these two distances the same as for the size of the rectangle to

In addition to horizontal and vertical constraints, you can also constrain the diameter of a circle or arc. This is not useful as a constraint today since the diameter remains constant as a default, however, once it has been constrained, you can use the *Edit* feature to change the diameter and this can be quite useful.

So far we have constrained geometry to fixed distances. In the current version of the software you can also use two variables, "W" for the width of the part and "H" for the height of the part. W and H can be used in formulas to define constraints. For example, W/2 when used to define a horizontal position will always position in the center of the part. W/3 is one third of the way across the part.

These formulas work using +, -, \*, and / and also understand parentheses.

## Working with Batch Input

### ***Working with Batch input***

*Batch Input* is used to combine cabinets and assemblies into a job without creating a custom layout. If you just want to output manufacturing reports or purchase for a group of cabinets and assemblies and do not need to display a layout, *Batch Input* is the simplest approach.

*Batch Input* is accessed through an icon in the top toolbar.

In its simplest form, you just add cabinets and assemblies to the batch. Select the cabinet, size and quantity.

Once added, a cabinet or assembly can be taken to the *Cabinet/Assembly Editor* and modified by clicking on the image of the cabinet.

Once modified, press *Return to Batch List*. A dialog allows you to specify how you want this modified cabinet treated. Note that the name of the cabinet has been modified by adding MOD and a number to it. You can rename this modified cabinet if you want.

If more than one of this cabinet was in the list, you can apply the change to all of them, or some of them or, you can bring the modified cabinet back into the batch as a new item. Press *OK*.

### ***Adding Cabinets to Batch Input Using an Excel Spreadsheet***

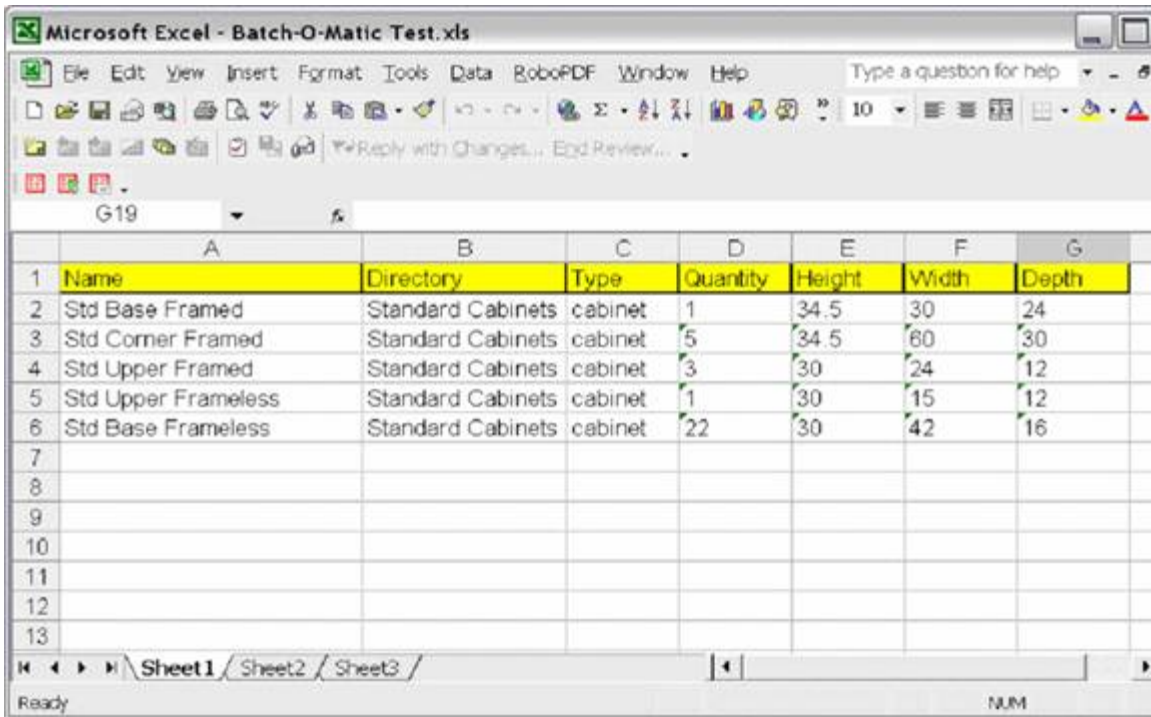

You can also use an *Excel* spreadsheet to input cabinets and/or assemblies to the batch.

This is done in two steps. First, we need to format the Excel spreadsheet properly, and then import it into the system.

In the Excel file you must provide the file name of the cabinet or assembly, the directory where the file is stored, the type (cabinet or assembly), the quantity of the cabinet or assembly you want, the height, width, & depth if you are loading a cabinet. The Height, Width, & Depth values are ignored for assemblies.

To load the Excel file into the batch, from the *Batch Input* area, click on the button labeled *Import Batch From Excel*.

Hear is an example of a properly formatted Excel file. The header information is not required, but may be used. If the header is used it MUST be done EXACTLY as shown in this example.

The screenshot shows a Microsoft Excel window titled "Batch-O-Matic Test.xls". The spreadsheet has a header row (row 1) with columns A through G. The header row is highlighted in yellow and contains the following text: "Name", "Directory", "Type", "Quantity", "Height", "Width", and "Depth". Below the header row, there are six data rows (rows 2 through 7) containing the following information:

	A	B	C	D	E	F	G
1	Name	Directory	Type	Quantity	Height	Width	Depth
2	Std Base Framed	Standard Cabinets	cabinet	1	34.5	30	24
3	Std Corner Framed	Standard Cabinets	cabinet	5	34.5	60	30
4	Std Upper Framed	Standard Cabinets	cabinet	3	30	24	12
5	Std Upper Frameless	Standard Cabinets	cabinet	1	30	15	12
6	Std Base Frameless	Standard Cabinets	cabinet	22	30	42	16

## Working with a Custom Layout

### *Working with a Custom Layout*

The *Custom Layout* area is used to create a three dimensional representation of the Job you are working on. This is accomplished by creating walls that represent the room or rooms where the job will be installed. Then you detail the walls and floor and install the appropriate cabinets and assemblies. When complete, you can view the layout from virtually any angle, output manufacturing data to help build the job, electronically buy the purchase items needed for the job, generate photo-realistic images of the complete job, estimate the cost and selling price for the job and generate a sales proposal for your customer.

As you can see, this is a powerful area and, as such, can get somewhat involved. We are going to show you the basic operation of the software in this section but we will also show, by example, techniques for using these features. In this area, perhaps more than anywhere else in the software, technique and imagination are important to the final result. We will try to show you basic techniques and build a foundation from which you can become even more creative.

Let's start with the basic layout of this area. *Custom Layout* is comprised of four working areas. The *Main* area is used to rotate, zoom and view the results. In this area you position the layout, hide walls and generally look at your results. The one function that is performed in this area is changing wall and floor textures.

From the *Main* area you can access a *Wall Editor* which is used to create walls. This area is also used to modify walls, change ceiling height, cut openings and holes in the walls and generally build the room or rooms where we will install the cabinets.

A *Detail Room* area is used to install cabinets, assemblies, display objects, lighting and generally create a realistic representation of the layout. Dimensions are precisely controlled in this area to make sure the cabinets and other items actually fit.

The final area of *Custom Layout* is called *Presentation View*. In this area we define light intensity and reflectivity of items in the room and generate photo-realistic representations including shadows and reflections.

### **Setting up Custom Layout**

We will start by setting up the *Main* page of the *Custom Layout* area.

Press the *Custom Layout* icon on the tool bar to open the *Custom Layout* area.

Right click in the center working area to bring up the menu. Select *Show/Hide* to open the dialog shown.

This dialog allows us to turn off display of certain items, but why would we want to do this?

If you begin working in *Custom Layout* placing cabinets with complex doors and pulls, you may find computer system response becomes quite slow. Some cabinets and assemblies may have components that are large and complex files. They consume substantial resources to render. When a number of these are in a single scene, even the fastest systems can slow to a crawl.

To address this, we can turn off certain items that render slowly, leaving the *Main* components, which is all we care about during the initial layout. When we are finished, we can turn these items back on to see the fully rendered final result.

*Show Lines* are colored lines (set the color in *Settings/Preferences* by default they are black) that outline edges of a cabinet to make the shape easier to see. At the beginning it is recommended that you hide doors, drawer fronts and pulls. These are typically the slowest to render although moldings and some *Display Parts* can also be slow.

## ***Setting up the Wall Editor Area***

When addressing the *Wall Editor* the first step is to set up the area. Press the *Wall Editor* button.

The system offers a background grid and a snap function that you can set. The background grid is used to visually locate items. The snap function causes the cursor to move from at fixed intervals rather than moving evenly. This assures you that every point selected is a number of fixed increments from any other point. For example, if you knew that every point on a wall was on even one foot increments, you could set the snap to one foot and the cursor would only access these one foot increments.

You can specify a different increment for the grid then you do the snap. A good starting point is to set the *Grid* to 12" and set the snap to 2". These are set to the left.

If the grid is not showing, right click in the working area and select *Show Grid* and the grid will display.

There are three different displays for the grid. The grid display is selected by right clicking and selecting *Grid Type*. Then select one of the available types.

*Dotted* displays a grid that consists of a single dot at each intersection of horizontal and vertical grid lines.

*Solid* displays the grid as solid vertical and horizontal lines.

*Dotted Line* shows the same grid using dotted lines instead of solid lines.

Right click and make sure *Show Origin* is checked as are *Snap* and *Object Snap*. You can modify these later when you become more experienced with the software but they are an important aide in the beginning.

Next, set the wall height and width. A good starting point is to set wall height to 96 inches and wall thickness to 4 inches. As a last item, you may want to open the *Settings/Preferences* area and change *Dimension Display* to *Feet, Inches and Fractions* because this is the format in which wall dimensions are normally available. Switching to this format may make interpreting wall dimensions easier.

## Creating Walls in the Wall Editor

We are now ready to create walls. Walls are created from above, looking down on the room. All walls are vertical and all walls are straight (no curved walls). Walls can be created either perpendicular to or at angles with each other.

Curved walls can be simulated by creating a large *Display Cube* in the *Cabinet Assembly Editor*, taking it to the *Part Editor* and creating a curved wall of the appropriate size. This will then need to be taken to the *Display Part Editor* to get a reasonable texture. This is a fairly involved process that should probably wait until you are proficient with the software. For now we will focus on straight walls.

If your room is rectangular, this is pretty easy. There is a rectangle tool that allows you to create a rectangular room as a one-step process.

If the room is not rectangular, you will need to create the walls one at a time which is the process we will demonstrate here. We will generate a somewhat complex room to demonstrate the various functions.

Click on the *Line Tool* icon at the upper left toolbar which we will use to create one wall at a time. We will start our wall at the lower left where the two red lines (X and Y axes) cross. This is the 0,0 position.

The position of the cursor is displayed in the dimension box located under the tool selection buttons. This display shows the X and Y position of the cursor as measured from the 0,0 position. The origin or 0,0 position is designated by the

crossing of the two red lines. These red lines are the X and Y Axes.

The X and Y Axes lines can be turned on and off by right clicking and selecting *Show Origin*. We will leave them on for now.

Move the cursor to the origin and click to anchor one end of the wall line to the origin. At any time before completing the wall, you can press the *Esc* key and abandon the effort.

Now move the cursor upward until you have a wall line that is 12 feet long. Click to anchor the other end.

Notice that there is a red arrowhead located in the center of the wall line. This tells you which direction the wall will be built. In this case, the wall will be built from the line to the left.

In this example, the walls will be built outward from the wall lines. Therefore, the wall line dimensions represent the *INSIDE* dimensions of the room.

In this example, the walls will be built inward from the wall lines. Therefore, the wall line dimensions represent the *OUTSIDE* dimensions of the room and the inside dimension will be reduced by the thickness of the walls.

You can change the build direction on any wall line by switching to the *Select/Move Mode* (the far left icon at the top with the arrow symbol) and highlighting the wall or walls you want to change. Then, right click and select *Reverse Build Direction*.

In addition to specifying the direction in which the wall is built, the red arrowhead also indicates the front active side of the wall. There is a default wall texture (which you can set) that is automatically placed on one side of a wall when it is created. The side of the wall line on which the red arrowhead is located will be given the wall texture and is considered the *Front* side.

You can work on both sides of the wall and you can add a texture to the back side, if needed.

After a wall has been placed, it can be deleted by highlighting it and pressing the *Delete* key.

Now, let's create a room.

From 0,0 we created a 12 foot wall upward. To create this wall, we simply used the mouse and watched the position display.

When it read 12' on Y and 0 on X, we clicked.

The next wall is 13'6" to the right.

This time we click on the end of the last wall and instead of using the mouse, we enter 13'6" in the dimension box for the X Axis and enter 12' in the dimension box for the Y Axis. This is the absolute position of the end of the second wall, 13'6" on the X Axis and 12' on the Y Axis.

You can change focus to the input box so you can enter the number by either moving the mouse and clicking in it (which also moves the wall until you input the numbers) or you can press the *Tab* key and type the number.

Pressing *Tab* again moves to the next box, pressing *Shift* and *Tab* moves back.

This defines the end of the second wall, which is at an absolute position of 13'6" on the X Axis and 12' on the Y Axis.

Press *Enter* and the wall line is created.

We now want a 30" long wall straight down.

This time we will use yet another approach. Change the mode from Absolute *ABS* to Incremental *INC*. In the Absolute mode we define a point by specifying its location with respect to the 0,0 origin. In the Incremental mode, we define a wall by defining a start point and then defining how far, from the start point, the end of the wall is on each axis.

Define the start point of this wall by clicking on the end of the last wall. Press the *Tab* key to activate the input box.

The dimensions we now enter in the X and Y boxes are the incremental distances from the beginning of the line rather than from the origin. In this case, we put a zero in the X Axis box, since there will be no movement along the X Axis. We put -30" in the Y Axis box, since we want to move 30" and we want to move in the minus direction. For the Y Axis, plus is in the upward direction and minus is downward.

Press *Enter* and the wall line is created.

Next we want a 4' wall line to the right. We will use yet another approach here.

Under the X and Y input boxes are two boxes labeled *Dimension/Angle*. These boxes display the distance and angle from the beginning of a wall line to the end of the wall line. In this case we click on the end of the last wall to establish a starting point. Then we enter 4' as the distance and 0 degrees as the angle.

Angles in the software follow a convention used by many popular CAD systems. Zero degrees is to the right and angles are measured counterclockwise. 90 degrees is straight up, 180 degrees is to the left and 270 degrees is straight down.

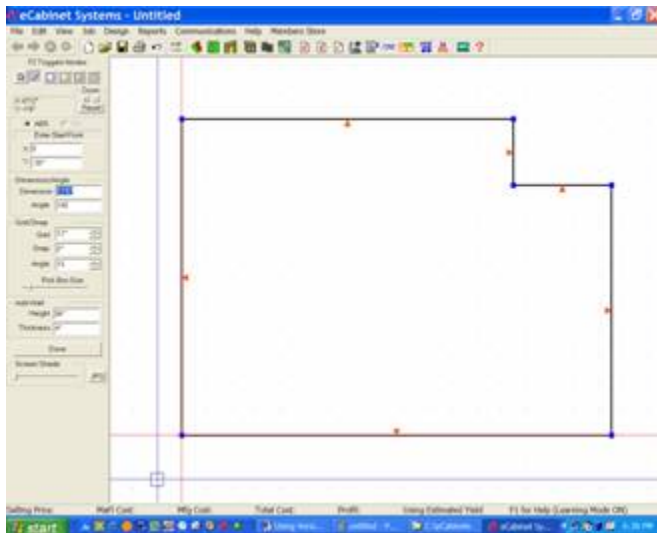

After we input the numbers, press *Enter*.  
The 4' wall line to the right is created.

There is another way to use this feature that may be a bit quicker. Click on the start point, pull a wall in the direction you want and click to create a wall. Don't worry about the length at this point.

When you click, the length box is highlighted. Type the length you want for the wall and press *Enter*. You now have a wall of the proper length in the proper direction.

Using this approach, the direction is supplied by the direction that the mouse is moved and the length is manually input.

Make sure *Angle Snap* is checked (right click and check it) before you use this technique to make establishing the angle with the mouse easy.

We will now use the mouse to pull a line down to the X Axis and create a vertical wall line and then we will close the room by connecting the end of the last wall to the beginning of the first wall, located at the origin.

The result is the wall line layout shown to the left.

## ***Adjusting Walls in the Wall Editor***

After the room has been created, any wall or walls can be adjusted or modified.

If you examine the toolbar at the upper left you will see a series of icons. The ones to the right are geometry tools we will work with shortly. The arrow at the far left puts the software into a mode we call the *Select/Move Mode*, probably because this is how we select and move things. To adjust an existing wall line, switch to the *Select/Move Mode* by pressing the *Select/Move Mode* icon (the arrow). You can also press F2.

Now, click on those items you want to modify. An item turns red when it is free to move. If the item is black, it is anchored and cannot move. This is important. Red moves, black doesn't. Although these instructions sound simple, you need to understand their application to get the results you want.

A wall line is made up of three elements, two end points and a connecting line. To move anything, you must release everything you want to move.

For the example shown, the left end of the top line and the top line itself are both selected and are red. The top of the left line is also selected but the left line itself has not been selected.

The left line will not change because the line itself is still anchored.

To move the left end, hold the *Shift* key, click and move the point using the right mouse button. Here you see the movement that occurs with the selections made above.

When we try to move the left end, the top line will pivot around the right end since the right end is still anchored.

Here we highlighted the top line and the left line. Both ends are freed to move.

upper left end and both the top line and left line will pivot around their fixed right end.

Here you can see that when we move the end point, both lines follow the point since both were highlighted and freed to move.

Next, we highlight the top line and both ends. This also highlights the top end points of the connecting lines to the left and right, however those lines will not move since the lines themselves are not highlighted.

In this case, the top line is free to move since the line and both ends have been highlighted. The lines it was connected to do not move since only the ends and not the lines themselves were highlighted.

In this case, the top line move. You may want to become familiar with

Now, in addition to the top line and ends, we have also highlighted the two vertical connecting lines.

as well as both connecting line spend some time experimenting to the operation of this area.

There is one final element to discuss in this area. By holding the left mouse button and moving the mouse, you can pull a red selection rectangle over the walls. Any line or node either inside or touched by this rectangle is selected. This provides an easy way to select one end of a room, for example, in order to move a wall out or in, you can pull a selection rectangle over the entire wall. The wall you are selecting with this rectangle is highlighted along with both end nodes, any connecting lines and the end nodes on those lines. When you move the wall, the wall line moves and any connecting lines expand or contract to stay connected to the wall line.

The next section demonstrates this in detail.

## ***Parametric Technique for Creating Rooms***

In the previous section we showed you techniques for adjusting walls in the *Wall Editor*. In this section we will demonstrate a technique for creating rooms using those tools.

The basic idea behind this approach is to draw the shape of the room using wall lines but without worrying about wall lengths. Then, when the room is complete, we adjust each wall to the correct dimension. Although this sounds involved, it is actually quite easy to do and for many is easier than trying to create each wall with the correct length from the start.

For this example, we will create the same room that was used as an example in the “Creating Walls in the Wall Editor” section.

We start by using the *Create Wall* tool and creating the basic shape of the room as shown. Set the *Snap Increment* to about 6” and turn *Snap* on so we can work with even numbers.

Now that we have the shape of the room, we need to make the walls the correct lengths. We will start with the shortest walls first, then we will adjust the main walls. We will start with the vertical wall at the upper right.

We will now switch to the *Select/Move Mode* (the arrow icon to the left) and pull a selection rectangle over the wall we want to move as shown. This is done by holding the left mouse button while pulling the rectangle over the wall. Using the selection rectangle automatically selects the top horizontal line, the two vertical wall

lines and the proper end nodes.

We now need to input the distance we need to move the highlighted wall to make our vertical wall to the right 30” long. This is actually quite easy. Put the length you want in the input box, then a minus sign and the move the cursor over the wall line to read the current length. Type that in the box right after the minus sign. We subtract the current length of the wall from the length we want, to get the incremental move distance.

Again, the formula is (the wall length you want) – (the current wall length).

We used the Y axis dialog box because we want to move the line down and the Y Axis represents up and down movement.

When you press *Enter* the top wall moves down until our vertical wall is 30” high. All other walls adjust correctly.

Next we focus on the short horizontal wall at the upper right. Press *Esc* to remove all highlights. Then, pull a selection rectangle over the vertical wall we want moved as shown.

The short horizontal wall should be 48”. Type this in the X Axis dialog box (X Axis because we want to move left or right). Place a minus sign and move the cursor over the current wall to see its length. Type this after the minus sign and press *Enter*. Both of our short walls are now the correct length.

Now we are going to adjust the overall height of the room. We will use the left vertical wall although the right vertical wall can also be used. When we adjust one wall we will actually adjust both and actually the formula for both will yield the same incremental move distance.

Press *Esc* to remove all highlights and then pull the selection rectangle over the top half of the room including both short walls we just adjusted as shown. We don't want those changing anymore.

We will use the Y Axis dialog box because we want to move the top half of the room up or down to adjust the height of the wall. Again, for the incremental move distance input the height you want minus the current height.

Finally, we will move the right half of the room. Again, we can use either the upper or lower wall to adjust the room. We use the selection rectangle as shown and for a move increment type the length we want minus the current wall length.

At this point the room is done.

Although this may appear involved, when you work with it a little it is actually rather quick and easy. In this relatively simple room creating individual lines requires six wall length inputs while this approach requires four, a third less. This difference can be even greater for complex rooms. Also, for complex rooms it may be easier to create the basic shape first and then dimension it rather than trying to work around the perimeter using individual walls.

## Changing Ceiling Height or Slope of a Wall

There are several other features for modifying a wall. We will use the left wall in the room we just created to demonstrate these features.

Change to the *Select/Move Mode* and highlight the left wall by left clicking on it. Now right click and select *Edit Wall*.

You are presented an elevation view of

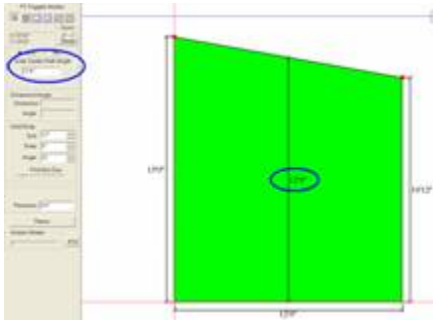

with the

wall. The two upper corners of the wall have handles that can be highlighted and moved. This adjusts the top edge of the wall.

To demonstrate, we highlight the upper left corner of the wall. Now, we can move it up and down using the mouse, or, we can input the new height for this side of the wall in the box labeled *Enter Left Wall Height*.

When the wall is first rendered, a display of the height of the center of the wall is also presented, in this case 9'.

If we now highlight the right corner of the wall, the entire top edge of the wall can be moved up and down without changing its angle. In this case, we specify the height of the center of the wall and the input box title has changed to *Enter Center Wall Height*. The top edge of the wall can also be moved up and down using the mouse.

To create a wall that has a center peak and slopes down on both ends, we break the wall into two walls aligned in a straight line and then slope the top of each in different direction.

To demonstrate, let's take both ends of our wall back to 8' and return to the *Overhead View*.

To return to the *Overhead View* you can either right click and select *Show Overhead* or press the *Return* button at the lower left in the control column.

Highlight the left wall and press *Delete*.

The wall we just deleted was 12' long so we will replace it with two walls, each 6' long.

Change to the *Line Tool* and create two walls, each 6' long as shown.

Now take each to the elevation view and adjust the right end of the bottom wall up and the left end of the top wall.

When the room is rendered, the two walls appear to be a single wall with a peaked center.

## ***Cutting Holes or Adding Sections to a Wall***

We can modify a wall by cutting holes in it or adding sections to it. These functions are done using geometry tools. These tools create shapes or geometry on the wall. This geometry is then highlighted and either cut from or added to the wall.

To demonstrate we will return to an elevation view of our wall, select the *Rectangle Tool* and place two rectangles on the wall, one for a door and one for a window.

There are several ways to define the rectangle.

You can use the input boxes, defining the X and Y position of the starting point and the X and Y position of the ending point of the rectangle. The lower left corner of the wall is always the origin or the 0,0 position. Plus X measurements are to the right of the origin and plus Y measurements are above the origin.

Another approach is to locate the first point using the absolute position and then switch to incremental *Inc* and input the X and Y size of the rectangle. Absolute position is measured from the origin or 0,0 point, the lower left corner of the wall. Incremental position is measured from the last point, not from the origin. In this case you will locate the lower left corner of the rectangle as measured from the origin. You will then input the measurement from this point to the top right corner of the rectangle. The second set of measurements is actually the size of the rectangle.

Finally, you could turn the *Snap* function on and use the mouse to manually define the rectangle.

It is also possible to create circle geometry. To do this we switch to the *Circle Tool* and place a circle on the wall.

The first point defined when placing a circle is the center. We can use any of the methods described above to define this point.

Then, the diameter is defined, either using the mouse or entering it in the *Diameter* box.

The final tool available is the *Arc Tool*. This tool creates a closed arc, that is, an arc with a straight line connecting the end points of the arc.

To demonstrate we will put an arched top on our wall. We will start at the upper left corner of the wall, clicking to define the first point.

The arc requires three points.

The first is the starting point.

The second is a point anywhere on the arc between the starting point and the end point.

The last point is the end.

For our second point, we will move to the center of the wall and place a point two feet higher than the wall.

For our last point, we will use the other end of the wall.

This is what our wall looks like after the geometry we just described has been added.

Once added, the geometry can be moved although its shape cannot be changed. To move it, switch to the *Select/Move Mode* and double click on a geometric shape. It turns red.

It can now be moved either using the mouse, or it can be incrementally moved by entering an X and Y incremental distance and the pressing

*Enter*.

The geometry will move that distance each time *Enter* is pressed.

Next, we will cut out the door, window and circle.

While in the *Select/Move Mode*, highlight the three geometries as shown.

Right click and select *Cut From Wall*. The geometry is cut from the wall. If the geometry extends off the wall, an open cut occurs. Geometric shapes can also be placed over or

touching each other. In this case, the outside perimeter of the entire area that is highlighted red is cut through.

Now, let's show how to add a section to a wall. In this case we will add the arch we created earlier to the top of the wall.

Highlight the arc geometry, right click and select *Add to Wall*.

The final result is a wall with an arched top and geometry cut from the wall.

At any time, when working with the wall, if the display does not appear correct, for example, holes partially filled in, it is likely that you have the *Level of Detail* set too low.

Simply press the *Enhance View* button and the display should correct itself.

The ability to cut holes in the wall can be combined with other features in the *Detail Room* area to offer a more realistic presentation.

To demonstrate we will cut a door opening in this wall and add a door frame.

From an overhead view of the room, bring up a wall elevation of the short horizontal wall at the top right.

Next, create a rectangle on this wall for the door opening. Here we specified a door opening 3' wide and 83" high.

We now cut this geometry from the wall and press *Return* to return to the *Overhead View*. We are now ready to address the next major area in *Custom Layout*, the *Detail Room Area*. We will continue this example in that area.

## ***Detailing a Room in Custom Layout***

The *Detail Room* area is used to add details to our room. This is done through four primary functions, placing and changing texture on the walls and floor, installing doors and windows on walls, installing cabinets and assemblies and loading and placing miscellaneous objects and items.

## ***Setting up Detail Room Area***

We start with the grid. The system offers a background grid that you can set and that can help when placing items on walls or in the room. You can set the increment for the grid. A good starting point is to set the *Grid* to 12". The distance between lines on the grid is set to the left.

If the grid is not showing, right click in the working area and select *Show Grid* and the grid will display.

There are three different displays for the grid. The grid display you want is selected by right clicking and selecting *Grid Type*, then select one of the available types.

*Dotted* displays a grid that consists of a single dot at each intersection of horizontal and vertical grid lines. *Solid* displays the grid as solid vertical and horizontal lines and *Dotted Line* shows the same grid using dotted lines instead of solid lines.

The next area is setting *move increments*. There are two *move increment* settings, one for objects and one for pan.

When working in this area you can move things in fixed increments using the arrow keys. The distance the item moves for each keystroke is the *Move Increment* for objects. This is adjusted by right clicking and selecting *Move Increment*, then select *Objects*.

You can also pan the entire display by an incremental distance. This is especially important when you have zoomed in on an area and need to move over a bit. The distance the display moves each key stroke is called the *Move Increment* for pan. This is adjusted by right clicking and selecting *Move Increment*, then select *Pan*.

We have already set up the *Show/Hide* dialog when we set up the *Main* page but you might want to revisit the settings when you begin working in this area.

## ***Placing Door and Window Images on a Wall***

The software supports the ability to quickly place images of doors, door frames, windows and window frames on a wall. It also allows an image to be placed in a window to simulate viewing an outside scene. There are more realistic ways of doing this but they are more involved. This approach is quick and rather easy and works well for many applications. We will cover the more detail approach later.

From the Overhead View in the *Detail Room* area, right click on a wall and select *Show Wall Elevation*. An elevation view of the wall is displayed.

Now under *Select Item to Install*, select *Door*.

You are now presented with a dialog where you can define the door you wish to place.

In the *Define Door* dialog, you set the *Width* and *Height* of the door as well as selecting a texture for both the door and the trim around the door. Notice that you can apply either the door or the trim or both. These door images are placed directly on the wall but you can set the checkbox so the image appears on both sides of the wall.

Experiment placing doors on the wall to get a feel for the process.

In the last section we cut a hole in our room for a door as the start of an example of a realistic door presentation. It is possible to use the trim around a door to trim out this opening and then add a *Display Panel* to simulate an open door creating a realistic appearance.

To do this, from an overhead view of the room, bring up a wall elevation of the short horizontal wall at the top right. We have already cut an opening into this wall. Under *Select Item to Install*, select *Door*. Set the size to 36" by 83", which was the size of the opening we cut in the wall. Select a dark image for the door trim.

Check *Show Trim* but uncheck *Show Door*. This will place the door trim but not the door itself.

Finally, check *Apply to Both Sides* and press *OK*.

Locate the door trim over the opening and click it in place.

Press return to the overhead view by pressing the *Return* button.

door opening with a dark door frame.

the addition of a *Display Panel* used to

*Panels* later. You could also create a *Object* of a door and use that.

We now have a realistic

It is shown here with simulate the door itself.

We will cover *Display* detailed 3D *Display*

Now let's look at handling windows.

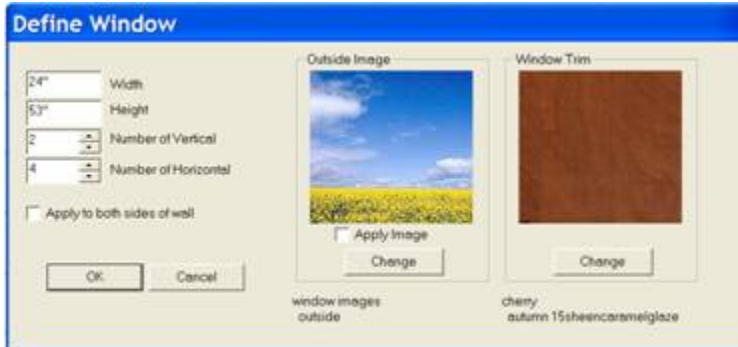

Windows work much like doors. To demonstrate, we will create two windows in the long horizontal wall across the top of our room.

The first will be placed in the conventional manner. For the second we will cut a hole in the wall and place it in a manner similar to the way we just placed the door.

Start by cutting a 24" by 53" hole in the wall in the *Create Wall* area.

Then go to *Detail Room*, right click on the wall and select *Show Wall Elevation*.

From *Select Items to Place*, choose *Window*.

We will address the open hole first.

Set the width and height (24" X 53") and set 2 vertical and 4 horizontal mullions.

Uncheck both *Apply to Both Sides* and *Apply Image* under the *Outside Image* display.

Press *OK*.

Place the window frame over the hole and click it in place.

Now, from *Select Item to Install* select *Window* again.

We want to place the frame on the outside of the wall, however, we do not want the mullions on this frame. Mullions on both sides of the wall doesn't look right.

Again input the size, but this time set the *Number of Vertical* and *Number of Horizontal* to zero.

Make sure *Apply to Both Sides of Wall* and *Apply Image* are both unchecked.

Press *OK*.

Now right click on the wall and select *Show Back*.

This is the back or outside of the wall.

Locate and place the window frame.

Press *Return* to return to the Overhead View and then press *Done*.

The result is a fairly realistic mullion window.

This creates a fairly realistic window but is somewhat involved.

There is a simpler approach that may be satisfactory for many applications.

Go back to the *Detail Room* area and select *Window* from the *Select Item to Place* list.

This time, add the mullions but also check *Apply Image* in the *Outside Image* area.

Note that you can take actual images of the outside and substitute them for the image presented here.

The result is a fairly good looking window, however, the perspective of the outside scene through the window is not correct except from a single elevation and the scene doesn't move as you move and rotate the room as it would in a real room.

It is possible to create more realistic appearance, especially when moving the scene around, by placing a copy of the outside scene on a large wall located a distance from the room. This is the approach used in Hollywood to create the illusion of outdoors. As you move around, the outdoor scene moves in the window, just like it would in real life.

For presentations to customers, it might be possible to take digital photos of their actual outside environment and place these on walls surrounding the room to offer an impressive and realistic presentation.

Windows applied in this manner are simply an image and are not three-dimensional objects. If you plan to use the *Presentation View*, which we will cover shortly, you may want sunlight coming through the window. In this case, you also want window mullions and mullions to shadow for a truly realistic presentation. To do this, you need to place the window using a different approach.

Instead of using the *Window* selection from *Select Items to Place*, select *Item* and then select *Doors/Drawers*. Press *Define Door* and select a *Conestoga – Frame Only – Mullion Door*. Set the mullion pattern for the window you want and save the door. Then Place the door in the room inside the rectangular opening in the wall.

Now, when you shine a light through the window the mullions will shadow properly.

There is another use for the *Window* function that can be quick with dramatic results and that is creating hanging pictures or paintings.

Create a window the same size as the painting, select an image of the painting as the *Outside Image* and position the result. The window now looks like a painting not a window.

As you can see, stunning results can be obtained with very little effort. There are thousands of art images available on the Internet and placing them in a room is very quick and easy using this technique.

All these decorative touches are actually both practical and useful because anything that enhances your presentation to your clients can help you compete and sell.

## ***Changing Wall and Floor Texture***

Wall and floor textures are specified and changed in the *Main* area. It is the only actual design function that is performed from this area.

We establish default textures in the *Custom Layout Parameters* area reached by pressing the *Custom Layout Parameter* button to the left.

These remain the default textures for this Job until they are specifically changed.

These define the texture that is used whenever a new wall is added. It also defines the texture initially placed on the floor.

Changing the default texture of the floor changes the floor.

Changing the default texture for the walls, however, does not change existing walls but only specifies the texture to be used on new walls.

You can change the texture on an existing wall and/or the floor, by right clicking and selecting *Floor/Wall Texture*.

The *Change Texture* selection brings up the *Change Texture* dialog.

Click *Image* to select a new texture from those available in the system. There are three ways that this texture can be applied to a wall.

*Auto Tile* has the system automatically determine how many rows and columns of the image should be placed on the wall. This uses the same functions used to apply wallpaper.

You can also select *Stretch* which stretches a single copy of the image over the wall. This is a very useful function which we will examine more carefully later.

Finally, you can specify *Manual Tile* where you specifically establish how many copies of the image are placed on the wall both vertically and horizontally.

We will start with the image shown and use *Auto Tile*.

If you hold the *Ctrl* key, the cursor turns into a paint roller. Now, any wall you click on

changes to the selected image.

If you click on the floor it will also change to this image.

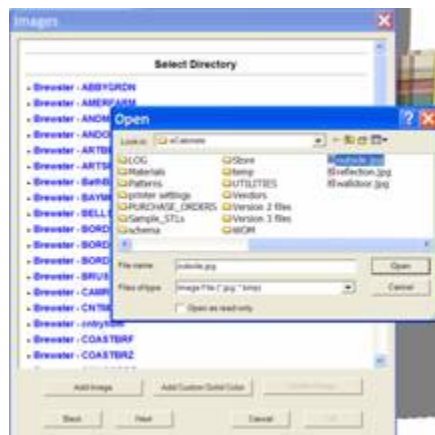

Now, let's switch to *Manual Tile* and specify 4 columns and 2 rows.

Hold the *Ctrl* key and click on the wall again. Although it looks a little strange, here is the result of our manual tile.

To demonstrate the *Stretch* selection, we will change the image.

Click *Image*.

From the *Image* dialog press the *Add Image* button.

this case we will use an existing however, you could import your

We will add a new image to those available in the system. In image own

image using this same technique.

From the available files, go to the ecabinets directory and select outside.jpg.

Images must be in the jpg format. Press *Open*.

In the dialog, type a new directory called *MyImages* and save the file in that directory.

Then page down to *MyImages* and select the image we just loaded.

Press *OK*.

Now select *Stretch*, hold the *Ctrl* key and click on the outside wall.

A single copy of the image is stretched over the wall.

This technique can be useful in trying to duplicate existing walls for remodeling projects. Shown here is a photo of a fireplace stretched over a wall.

This technique creates a rich visual effect that cannot be duplicated with strictly computer generated images.

This image was shot with a digital camera.

The original image was 1600 by 1200 pixels. This is too large for easy use so we used the *Image Control* (IrfanView) program incorporated in eCabinet Systems to *Resize/Resample* the image.

We set the new size as 20% of the original being careful to check *Preserve Aspect Ratio*.

Then, we cropped the image, also using the Image Control software, to include just the fireplace.

We then loaded the fireplace image in the same manner as the outside image earlier.

Images used in this manner can be prepared by almost any imaging software but must be in the jpg format and, as a general rule you should try to keep them under 1,000 pixels in each direction. You should also try to keep the aspect ratio of the image

about the same as the aspect ratio of the wall it will be stretched over to keep from noticeably stretching it.

This same technique works for the floor.

You can stretch an image on the floor in the same manner as the walls by simply holding the *Ctrl* key and clicking on the floor instead of the walls.

This capability is especially important when trying to reproduce plank flooring.

There are several full size room floor images in a directory called *Floor Images*.

These are intended for a room 12 to 15 foot square but tend to provide acceptable results for residential rooms up to about 30' long. Files are available for floors running left to right.

These same images have been turned 90 degrees to provide for floors that run front to back.

The fireplace shown previously displayed the fireplace and hearth as a single 2D image.

It is also possible to make the hearth a *Display Cube*, using an image of the actual hearth bricks.

This results in an even better presentation as seen here. This is especially noticeable when the room is rotated and moved or displayed in *Presentation View*.

We demonstrate the use of *Display Cubes* in the section titled “Working with Display Cubes”.

## ***Installing Appliances***

Next, let's discuss appliances.

In the *Select Items to Install – Items* area, there is a category for *Appliances*.

These are generic three dimensional appliances that are placed much like cabinets.

They can be resized to simulate various appliances.

They do have the advantage that the software knows they are appliances. Therefore, the clearances set in *Standard Dimensions* are applied when they are installed. The disadvantage is that the selection of designs is somewhat generic and limited, and you may want a more accurate representation of appliances your customer plans to use.

The software offers a way to simulate almost any appliance that is essentially rectangular.

In an earlier section we showed you how to simulate a fireplace hearth using a *Display Cube*.

A *Display Cube* can also be used to create an appliance.

Go to the web site for the appliance manufacturer and get a front view jpg image of the appliance.

Then create a *Display Cube* of the correct overall size and map the image to the cube.

Although the result is flat, it does a fairly good job of simulating a wide variety of appliances.

Shown here is a dishwasher, cooktop and double oven created using this technique.

As you can see, the overall effect is quite acceptable.

One trick that lets you use the standard clearances for appliances and yet install *Display Cube* appliances is to install one of the generic appliances of the correct size and then install the cabinets around it. Then delete it and replace it with the *Display Cube*.

## ***Adjusting Installed Cabinets in Custom Layout***

We will now look at some additional features of the *Detail Room* area and discuss changes that can be made to installed cabinets.

If you highlight a cabinet and then place the cursor over a wall, the length of the wall is displayed along with the distance from the cabinet to the wall as shown.

If you highlight two cabinets, the distances between them, X, Y and diagonal, are displayed.

We will explore the *Adjust Cabinet Features* by starting with a single cabinet on a wall. Highlight the cabinet, right click and select *Adjust Cabinet Features*.

All of the menu selections are applied to a cabinet or cabinets that have been installed and highlighted.

Let's look at the selections, one at a time.

The first selection is *Change*.

This is normally used to change doors, drawers or pulls in a kitchen.

To use this feature, first change the default door, drawer front and/or pull selection.

To do this you must enter the *Door/Drawer Front Designer* from the *Door/Drawer Editor* in the *Cabinet/Assembly Editor*.

Only if you enter through this area is the *Set Default* button available.

Once the default has been changed, we need to highlight all the cabinets we want to change. Then it is a simple matter of selecting what you want to change.

The next feature is called *Autofill*.

*Duplicate Left*, *Duplicate Right* and *Autofill* are three forms of essentially the same function. These functions only work in the *Overhead View*.

These only work if you have a single cabinet highlighted.

*Duplicate Left* places exact copies of the highlighted cabinet to the left until reaching a bounding wall, cabinet or appliance. This is essentially the same as if you continued to place cabinet on the left until you reached the wall.

Unless you are incredibly lucky, eventually you will end up with an opening that the cabinet doesn't fit.

In this case, the cabinet symbol shrinks to fit the opening as shown.

This also happens if you place cabinets manually, one at a time or if you use the *Duplicate* or *Autofill* functions.

If using the *Duplicate* or *Autofill* functions, however, the system asks if you want to re-size all the cabinets to the same width.

This re-sizing function is also available as a separate command within the *Re-Size/Equalize* menu selection which we will discuss shortly.

Here is another common occurrence. The cabinet we are placing is too narrow for the available opening.

To handle this, there is a selection called *Expand to Fill*.

When selected, this expands the highlighted cabinet to exactly fill the space it is in.

This might be a good time to mention the hot keys shown to the right of the various menu selections.

Pressing these keys is the same as making selections from the menus.

Once the key sequences are known, most functions can be performed much faster and easier using hot keys.

For example, in this case, you highlight the cabinet and type *SJX*.

For anyone that plans to use the software extensively, it is worth the effort required to learn the hot keys. There is a chapter in this manual that discusses the hot keys in detail. Until then, you can access a list of hot keys and their use from the *Help* menu at the top.

The next area we will discuss is the *Cabinet End* selection.

For installations where the end of a cabinet is exposed, many cabinetmakers add an applied end.

The software supports two types of applied ends, a material selection or a door design.

The dialog shown is used to define the applied end.

The *Scribe* area only applies to face frame cabinets. This area is used to adjust the scribe or the amount that the face frame stile extends past the outside edge of the cabinet.

When an applied end is placed on a cabinet, many times we want the face frame to extend over the edge of the applied end.

Rather than going back to the *Cabinet/Assembly Editor* and making this change, it can be adjusted here.

The next function, *Insets* are used to make the applied end either larger or smaller than it would normally be. Normally, the applied end will be the width and height of the cabinet end on which it was applied.

If you specify an inset for one edge, top, bottom, front or back, the corresponding edge of the applied end will be inset, or made smaller, than the original size. If you specify a negative inset, that edge is made larger or extended. In this way you can adjust the applied end for a variety of applications.

For example, you could have two base cabinets installed back to back as an island as shown.

Then, on one of the base cabinets, place an applied end with a negative inset so that it extends over the end of the adjoining cabinet. In this case, we set the *Back Inset* to minus number so it covered the ends of not only the original cabinet but also the adjacent cabinet.

Moving down the list of available commands, the *Edit Cabinet* selection can be a useful feature.

*Edit Cabinet* takes the cabinet to the *Cabinet/Assembly Editor* where you can modify it.

Then, the modified cabinet is brought back into the room.

While in the *Cabinet/Assembly Editor*, you can save the modified cabinet under a new name Although it not necessary, it is usually a good idea in case you need to use the modified cabinet again.

Otherwise, you can simply make the changes, bring the cabinet back to the room and only this one cabinet in this room is changed.

The *Merge/Separate* command is not functioning in this version.

Its planned function is to merge two separate cabinets into one, substituting a single common end between the two cabinets instead of a separate end for each. The developers have left the menu selection here since they plan to add this feature in an upcoming update.

highlighted cabinet.

Next is the *Re-Size/Equalize* command.

Again, this command only applies to cabinets that have already been installed and have been highlighted.

The actual function of the command depends on what is highlighted.

If a single cabinet is highlighted when the function is called, the dialog shown appears.

This dialog is used to change the size of the

Notice that for each of the parameters, not only can you set the size, but you can also specify which side moves to accomplish the size change.

If you choose *Both* for any of the dimensions, the center remains fixed and both sides move an equal amount.

If you highlight two or more adjoining cabinets as shown, and then press *Re-Size/Equalize*, the total width of all cabinet is maintained but the cabinets are each

resized so that they are all the same width.

If you highlight an upper and base cabinet as shown and select *Re-Size/Equalize*, you have several choices.

If you select *Equalize*, both cabinets are made the same width and positioned directly above and below each other.

The cabinet that is specified as *Anchor* does not move. The other cabinet moves directly in line.

If you select *Align Left, Right* or *Center*, the cabinets are aligned above each other as specified without adjusting the width of either. Again, the *Anchor* cabinet does not move.

## Working with Display Cubes

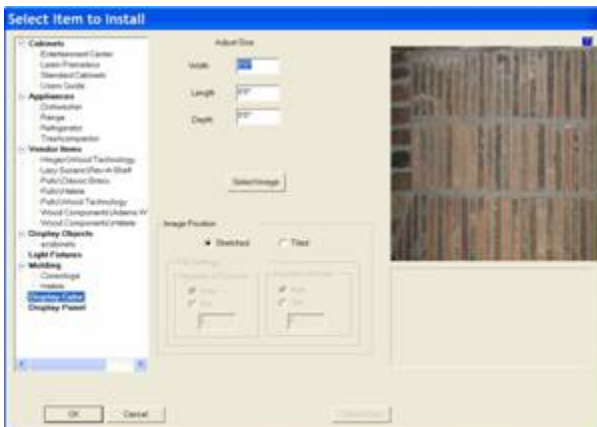

A *Display Cube* is essentially a cube, of any size on which we can place a texture image. It is one of the most powerful tools you have for creating realistic custom layouts. It can be used for pillars, beams, hearths, rugs, appliances, fireplaces, cereal boxes, books and a thousand other common items that will make your presentation better. They can even be created in the *Cabinet/Assembly Editor* taken to the *Part Editor* and machined into almost anything.

The best way to learn the use of *Display Cubes* is to run through some examples. Earlier, we use display cubes to simulate a fireplace hearth. Let us see exactly how we did this.

From *Detail Room*, select *Display Cube* from the list under *Select Item to Install*.

The dialog to the left appears.

In this case, our digital images were of a

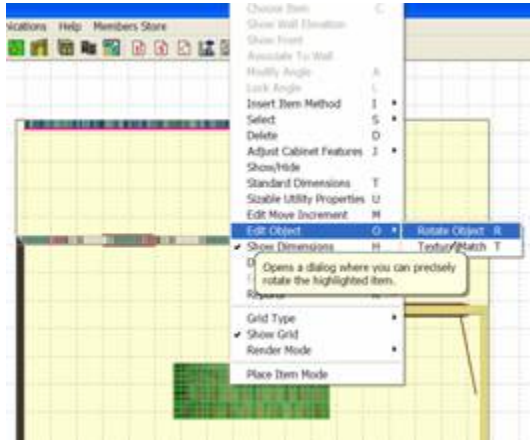

six foot section of the hearth so we will create two display cubes.

We took the original image of the left side of the original hearth and flipped it horizontally to create a second image we will use on the right cube.

Although this image appears compressed, the original image was long and narrow. The software compressed it for display here but will use the original image for the cube.

In this case, we will set the cube width to 6' and the length to 2'.

The reason that we do this is that the width is the left to right dimension and the length is the up and down direction.

Our image is compressed but the original long dimension is left to right so we make that the 6' dimension.

Check *Stretched* to indicate how the image is to map to the cube and then press *OK*.

The cube appears in the room, at floor level

and highlighted.

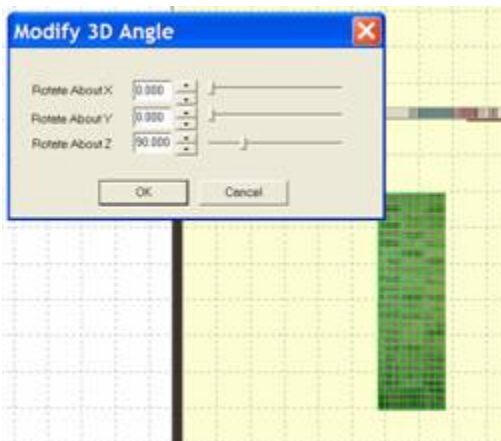

The first thing we want to do is rotate it 90 degrees.

Right click, then select *Edit Object* and *Rotate Object*.

This brings up the rotate dialog.

We want to rotate about the Z axis 90 degrees.

If you click on the slider, it will move in 90 degree increments.

The hearth is now properly rotated and since it is already on the floor, it is ready to move into position.

If the height above the floor was not correct, it can be moved up and down using the *U* and *D* keys, *U* for up and *D* for down.

It moves the *Edit Move Increment* each time a key is pressed.

We can now move it into position to the lower left of the wall by holding the *Shift* key and using the right mouse button.

It can also be moved by holding the *Shift* key and using the arrow keys.

Here the first half of the hearth is in position.

Double click on it to deselect it.

to select the

Here you see both

Double click on  
highlight and

Repeat the process for the second half of the hearth, making certain second, right hand image.

halves of the hearth in position.

the second half to remove the  
press *Done*.

The result is a realistic hearth made of two brick image covered *Display Cubes*.

When a *Display Cube* is created, the image selected is placed on all six sides.

It is stretched and skewed as needed so that one copy of the image is placed on each surface.

Sometimes you need a cube that has a different image on one surface or another.

For example, you may need a special range, which is a three dimensional object that has a different image on the top and front.

In these cases, you may need to combine two or more *Display Cubes* to get the effect you want.

To demonstrate, we will develop a gas range using images obtained from the web.

Here you see an image of the range we would like to simulate.

It is shown loaded into *IrfanView*, which is the image control software that starts when you press the *Image Control* icon on the toolbar. Everything we do to images in this manual is done within eCabinet Systems using this software.

If you look closely, you will see that we have pulled a highlight rectangle over the very front of the range.

We will crop the image to this area and save it under a new file name.

Then we will do the same thing to the backsplash.

For the top, we could not find the exact range top but we found one that is similar and will use it.

Since it is black, details will not be all that visible.

The overall accuracy of presentation is dependent on each user and you need to make decisions about what is and is not acceptable yourself.

Now we will create the first cube, which is the range body itself.

One area that can be confusing is determining how to map the image to the actual cube for use in the room.

The diagram to the right shows the cube as it sits in the room.

The front surface is the *Width* and *length*.

The *Depth* is the distance front to back, just like the cabinets.

first displayed, it will be turned X Axis with the front face

When the cube is 90 degrees on the facing upward.

You need to turn it 90 degrees you can use it.

as shown before

This is the easiest way to get the looking for.

effect we are

If we try to create the cube already in the correct orientation, the image will be upside down requiring even more manipulation.

Now we move it to the wall as shown using the *Shift* key and left mouse button.

We then right click on the wall and select *Associate to Wall*.

We are going to adjust the height of the range from the elevation view of this wall.

For the range to display in the elevation view of the wall it must be associated to the wall.

Next, right click on the wall again and select *Show Wall Elevation*.

The range is actually located partially under the floor.

This is because it was first generated on the floor and when we rotated it, the height of the range was greater than the depth so part of it rotated under the floor. This will occur many times when working with *Display Cubes* so be prepared for it.

You can move it up by holding the *Shift* key and using the left mouse button. (Make sure you are in the *Free Style* mode). You can also use *Shift* and the up arrow key.

Here we see the range and the front looks pretty good but the top clearly needs help.

Using the same technique, we will create a top using the range top image.

It will only be an inch deep.

We will also create another cube for the backsplash and use the backsplash image we took from the original range image.

Here is the completed range made from display cubes.

We added additional cubes 2x2x5 with the backsplash image to create the feet.

The result is very pleasing and adds to a customer presentation.

This particular appliance was developed in the *Custom Layout* area. You could also create it in the *Cabinet/Assembly Editor* and save it as an assembly. This might actually be easier since positioning *Display Cubes* in space is easier in the *Cabinet/Assembly Editor* than in *Custom Layout*.

*Display Cubes* can be used to simulate a wide variety of items in a room. They can be used for beams, pillars, doors, ceilings, etc.

As noted earlier, cabinets will not obey the clearance settings for appliances specified in *Standard Dimensions* when appliances are created in this manner.

If you want to use this feature, you can size and place the system appliances and then after the cabinet have been located, delete the system appliances and replace them with these *Display Cube* appliances.

## ***Working with Floors and Rugs***

Texturing the entire floor is covered in the section “Changing Wall and Floor Texture”, however, at times this simple approach is not adequate. In those instances, *Display Cubes* can be used to simulate wood floors and rugs and offer almost unlimited flexibility.

When you select a texture for the floor, the image is tiled, that is stacked in rows and columns to create the floor texture. This works well for tile, stone and parquet patterns but does not work well for wood plank floors.

You can stretch a floor image across the floor in the same manner as with walls. This, however, stretches the floor image over the entire *Custom Layout*.

There are times you may want to create a multi room layout with different floor images in each room. Or, you may want a different floor appearance in one section of a room or a hall.

The only way to get a different floor images in the same layout is to develop an image of the floor in each area and then map that image to a thin *Display Cube* that is laid on the floor.

There are a few of these large wood floor images in the software in a directory called *Floor Images*.

These images generally work for rooms of 15' x 15' or so.

You can generally expand the image along the length of the boards with little ill effects to about 30' or so. If you expand the width, the boards will seem wider in the room. If you place them across a room smaller than about 15', the boards seem narrower.

If you must maintain board width on a narrow room, you can crop the image and save the cropped image as another file and then use it for your room. You can do this in the *Image Manager* area.

If you need a wider image you may be able to duplicate the existing image and paste several together.

The process of placing the floor is straightforward.

Create a cube the size of the room and .1” thick.

This is thin enough it will have virtually no effect on the height of the floor.

Then map the wood floor image to the cube using the *Stretched* selection.

Position the cube in the room and you have a fairly realistic wood floor.

Since the bottom of the cube is automatically placed on the floor

when it is created, all you will need to do is slide it into position from overhead.

The room shown also has a decorative rug.

This is also made of a *Display Cube* covered with the image of a rug obtained from the Internet.

When creating rugs to place on *Display Cube* floors, make the cube thickness .2” instead of .1” for the rug itself. This assures that the top surface of the rug cube will be above the floor cube and that the rug will be visible without having to move it up.

When working with a client, you can take digital photos of existing rugs and possibly even floors and incorporate these in your presentation. Just make sure that you take the photo from above looking down to get a front-on view.

This same idea works for unique paintings or other works of art.

*Display Cubes* and *Display Panels* and the image display features are valuable and powerful tools and over time you will find many, many uses for them.

## ***Working with Countertops***

### **Working with Countertops**

There are two different ways to develop countertops. Most countertops will be developed in the *Detail Room* area of *Custom Layout* using the *Countertop – Add/Modify Countertop* command. This opens an area where countertops are defined and built. This represents the quickest and easiest way to develop countertops for a layout.

A second approach is to create a display cube of the correct size, shape and thickness and apply a countertop texture to it. This *Display Cube* is then moved and located above the cabinets as a countertop. This process is more involved than the countertop interface however, it can also be more flexible. Generally this approach is used when the standard countertop approach cannot reproduce a countertop because it is unique or different.

## **Adding Countertops Using the Add Countertop Command**

In this approach, we will use a countertop dialog accessed from the *Detail Room* area of *Custom Layout* to define and refine countertops.

The basic approach is to use the countertop dialog to define and locate the basic countertop or countertops. A waterfall front edge can also be defined in this area. All other edge profiles and machining operations such as front edge profiles or cutouts for sinks are done by exiting the countertop area and from the *Detail Room* area taking the resulting countertop to the *Part Editor*. We will look at each of these operations in the following examples.

Countertops in this area are developed using a *Countertop Stock* material that is defined in *Settings/Preferences*.

We start by placing all the cabinets in our room. Then from the *Detail Room* area, right click and select *Countertop - Add/Modify Countertop(s)*. You are presented with an overhead view of the cabinets.

Press *Construct Countertop*. A step by step guide is shown throughout this process at the center left of the screen to guide you through each step. The first instruction is “*Select points to create the outline of the Counter Top*”.

Moving the cursor over the cabinets will display nodes that can be selected. Press “M” to see all the available nodes.

We are now going to outline each individual piece of the countertop. Each outline will be handled as a separate piece of the countertop. We will develop each individual section, one at a time. Click on nodes to create a closed outline around the first countertop section. When you close the outline, a dialog appears where you can define the countertop for this section. This countertop section can span openings between cabinets (for under counter appliances for example).

In the dialog you can specify a countertop material for the countertop itself and, if it exists, for the backsplash. The countertop and backsplash do not need to be the same material. The last material used is presented as a default.

It is also possible to add a waterfall to the front edge of the countertop by checking *Add Waterfall*.

*Height* is the height above the surface of the countertop of the highest point of the waterfall.

*Radius* is the radius of the main rise of the waterfall edge. This must be less than the sum of the material thickness added to the *Height*.

*Blend* is the percent of the main radius used to blend the main radius with the countertop surface. The higher the percentage, the more gentle the blend. Blend % is normally over 100%. Please refer to the diagram.

If you want the countertop to overhang the cabinets, check *Add Overhang*. Use the dialog boxes to specify an overhang dimension for each edge of the countertop.

The system tries to determine which edge is the front, back, left and right and most of the time it gets this correct. Should you need to modify these, press *Designate Edges*.

You can then set any edge by right clicking on it and selecting the edge you want it designated as. Note that a waterfall edge is placed on the front edge of a top and a backsplash can be placed on the back, left or right edge. A *Front Splash* can be placed on the front edge of a countertop provided it does not have a waterfall edge.

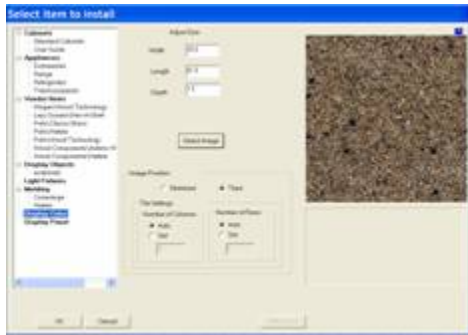

All splashes are located above the countertop. To create a countertop with a descending edge, create a countertop material that is as thick as the top and edge combined and make the countertop from this material. Then, in the *Part Editor* pocket out the underside behind the descending edge to make the countertop the proper thickness. If you just want the proper “look” in the front, you can just leave it full thickness.

Any other edge treatment, sink cut outs, etc. can be added to the countertop by taking it into the *Part Editor* and modifying it.

## Adding Countertops Using Display Cubes

In addition to the *Add Countertop Command* covered earlier, *Display Cubes* can also be used to create countertops. Countertops can simply be rectangular cubes with the correct texture image. Complex countertops can be created by processing these *Display Cubes* through the *Display Part Editor*.

To demonstrate this approach we will use some examples. In this first example we are creating a simple rectangular top to place over a set of two cabinets.

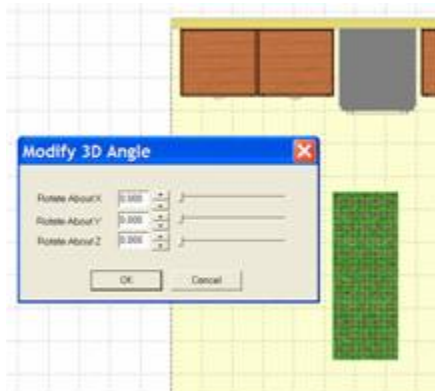

In the *Detail Room* area, Main page, under *Select Item to Install* select *Item*.

Then select *Display Cube*.

Input the size and then press *Image* to select an image for our countertop.

Press *OK*.

The *Display Cube* function places the top in the center of the room at floor level. You will need to orient the top to the cabinets and raise it to the proper height above the floor. Then it is moved into position.

In this case we need to spin it around 90 degrees to orient it properly with the cabinet. From the *Right Click Menu*, select *Edit Object – Rotate Object*.

This brings up the dialog shown.

Spin the top 90 degrees on the Z Axis.

It is now ready to position.

We will next cover positioning of the countertop in detail to show some common techniques.

Here we moved the countertop using the *Shift* key and right mouse button to a position near where it will eventually be.

We have not moved it totally into position because it is located on the floor.

If we move too far, we will place it inside the cabinet where we will not be able to highlight it when we switch to the elevation view.

The next step is to associate the countertop to the wall so it shows up on the elevation view of the wall.

Since the countertop is already highlighted, right click on the wall and select *Associate to Wall*.

Then right click on the wall again and select *Show Wall Elevation*.

Here we see the countertop, highlighted on the floor in the elevation view.

There are a couple of ways to move it up to the top of the cabinets.

The first, and probably easiest, is using the *Edit Move Increment*.

From the *Right Click Menu* select *Edit Move Increment* and change it to 34.5”.

This is the height of the cabinets.

Since the *Display Cube* is initially placed on the floor, moving it up 34.5” will place it at the top of the cabinets.

Simply highlight the cube and while holding the *Shift* key press the up arrow key one time.

The countertop is now at the correct height.

We can also use the *Shift* key and mouse to move it to the top of the cabinets if you are operating in the *Free Style* mode.

When you get close, press the *Ctrl* key and pull a blue rectangle over the top corner next to the range.

The view will zoom as shown.

Now, from this zoomed view, accurately position the countertop over the cabinet edge.

Then press the *Return* button to return to the overhead view. We again want to zoom in, this time on the back corner, next to the range.

Hold the *Ctrl* key, pull the blue rectangle to zoom as shown.

Highlight the countertop and move it precisely into position over the corner of the cabinet and up against the wall.

Press *Home* to return to the original zoom view.

We now have a countertop on the two cabinets as shown.

If you want, you can create another *Display Cube*, using the same image, to simulate a backsplash as shown.

Although at first, this appears to be quite involved, with just a little practice you will be able to place and locate these very quickly.

Now let's address a countertop with a sink.

There are two approaches to this. We can't simply move the sink over a countertop because, unless we cut a hole in the cube, it will show in the center of the sink.

In the first approach, we place the sink and then place several cubes around it to simulate a countertop.

Start by moving the sink into position over the sink base.

We now simply create four separate *Display Cubes* which surround the sink, using the techniques just covered.

We also add a *Display Cube* as the backsplash.

Here is the finished sink side of our layout with the countertop and sink in place.

Another approach you can use for countertops is using *Display Panels*.

A *Display Panel* is similar to a *Display Cube* except it is a rectangular piece of a material we defined in

*Settings/Preferences*.

To use a *Display Panel* as a countertop we first need to create a new *Sheet* material the thickness of the countertop.

Then we must select the proper image for the material.

Now, define a *Display Panel* instead of a *Display Cube*.

The process is almost identical and the final result is essentially the same.

The only real difference is that by using *Display Panels*, the countertop pieces will be nested in the countertop material.

When using *Display Cubes*, no nesting occurs and the cubes are used strictly for display.

If you have a use for the nest information, use *Display Panels*. If not, use *Display Cubes*.

Once the countertop has been installed, you can change its texture using the *Texture Match* command, but you can only change it to a texture that already exists in the drawing.

This is not really a problem but does require some technique.

Create a small *Display Cube* with the texture you want.

Place this in the room.

Next, highlight the countertop and from the *Right Click Menu* select *Edit Object – Texture Match*.

Now click on the new textured cube.

The highlighted countertop will change to the new texture.

You will need to change each *Display Cube* or *Display Panel* in the countertop, one at a time.

Once the entire countertop is changed, you can delete the cube you used to carry the texture image.

The *Part Editor* offers us another way to develop countertops using *Display Cubes*. This is a little more involved but can produce fairly complex countertops.

In this approach, we will create the entire countertop as a modified *Display Cube*. Then, we will export it to the *Display Part Editor*, texture it and turn it into a *Display Part*.

To do this we must return to the *Cabinet/Assembly Editor* and load a *Display Cube* large enough to cover all the cabinets. In our example, we create a cube that is 14' wide, 10' long and 2" thick.

Next, highlight it and take it to the *Part Editor*. Using the geometry tools and contour, cut the panel to the countertop shape you need. Notice you can cut out sink openings and even put radiuses in the corners.

You can also put a profile along the front edges if needed.

Take these changes back to the *Cabinet/Assembly Editor*.

Probably the first thing you will notice is that it is the correct shape but it doesn't look very good. That is because, in this area of the software, texturing is automatic and is generally optimized for rectangular panels. These settings do not always work for randomly shaped pieces.

To correct this we will *Export* the *Display Cube* as an HSF file, load it into the *Display Part Editor*, adjust the texture and then save it as an HSF *Display Part*. We can then load this *Display Part* directly into our *Custom Layout*.

Start by pressing the *Home* key to access a straight on front view. If the item or items you are exporting are rotated, they will be copied in a rotated orientation and will be in that orientation when you load them into *Custom Layout*.

Once oriented properly, highlight the countertop by clicking on it. Then, from the *File* menu at the top, select *Export Selection*. This will export anything currently highlighted. If more than one item is highlighted, they will all export as a single HSF and become a single *Display Object*.

Specify a directory and name.

Now, go to the *Display Part Editor*. There is probably no reason to save the modified cube in the *Cabinet/Assembly Editor* since the texture is wrong and we already have the shape saved as an HSF.

Load the file. The texture should already look better. Generally with countertops, increasing the *Texture Scale* to 10 or 20 improves the appearance.

Once you have an image you are satisfied with, save it and you are ready to add it to your *Custom Layout*.

Note that during the save process you can specify that the countertop be added to the *Cut List*. You can also input a cost for the countertop that will be added to the *Material Cost* for the job. This is a great way to allow for the cost of countertops when estimating the

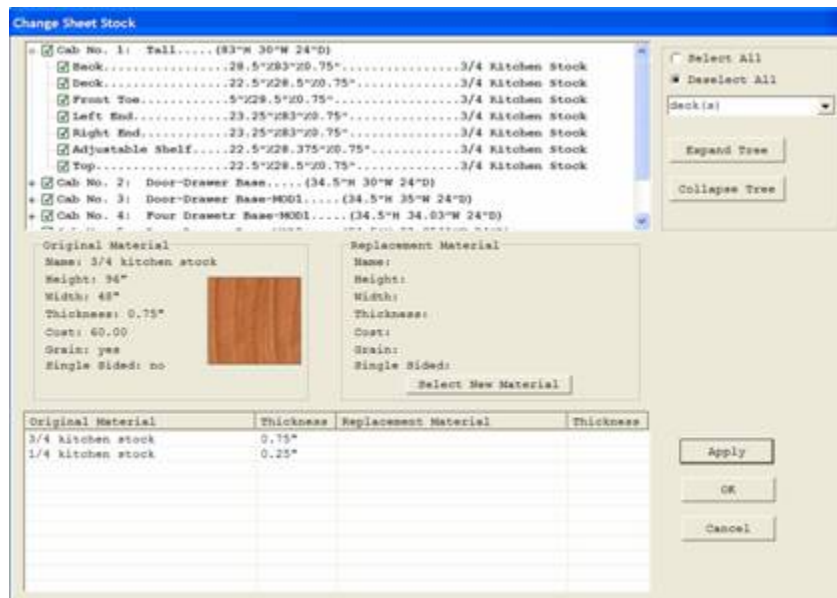

cost of a job. See the chapter on *Estimating Costs* for more information about tracking costs in the software.

This basic approach can be used to create *Display Objects* within eCabinet Systems without the need for a separate CAD system. It also allows you to modify the appearance of *Display Objects* that you obtain from others. Simply *Export* the *Display Object*, modify the appearance in the *Display Part Editor* and then save it again.

## Change Material for Cabinets in a Custom layout

You can change the material used in the cabinets currently installed in the layout. This allows you to see how different textured material might appear or to see how material with a different cost would affect the overall cost of the Job.

This feature is accessed by right clicking and selecting *Change Materials* then selecting *Sheet Stock*.

This opens the *Change Sheet Stock* dialog.

With this dialog, you can change the sheet stock used for the entire job or you can substitute the material used on any part or combination of parts.

There are two steps to this process. First, you designate the part of parts you want to change. The materials

currently used in those parts are then displayed. Then, you specify the material you want to substitute for the existing material.

The first step, selecting or designating the parts you want to change, starts before you enter this dialog. In the room layout, highlight the cabinet, cabinets or items you want to modify. If you do not highlight anything, all items in the layout are displayed in the dialog.

The cabinets are displayed in a tree structure. When you expand this structure you can select specific parts to be changed for each cabinet, or you can specify the entire cabinet.

An area to the upper right helps you make this selection. If you check *Deselect All* and then click on *Backs*, the system will deselect all backs on all cabinets. If you want to select all backs and nothing else, check *Deselect All* and then click on *All Parts*. This deselects all parts of all cabinets. Then, check *Select All* and click on *Backs*. This will select all backs on all cabinets.

Once you have selected the parts you want to change material on, a listing of materials currently used is shown at the bottom. Highlight a material and you will see a complete description of the material above the list. To the right of that description you can specify the material you want to substitute for the existing material.

Once you have selected the replacement materials for each of the existing material, press the *Apply* button and the substitutions are made.

This action does cause a regeneration of the cabinet or *Display Panel* so, any modifications made to these parts by the *Part Editor* will be lost. We hope to address this area in future builds to eliminate this however, in the current version regeneration does remove editing from part designs.

## ***Generating Photo-realistic Images using Presentation View***

*Presentation View* is a sophisticated presentation program that can generate photo-realistic views of your layout. These images are valuable when trying to sell a job to a potential customer.

The purpose of the *Presentation View* is to try to develop as realistic a presentation as possible. To make this work, we will set it up much like you set up a scene in a photographer's studio or like you might arrange a set for a play or movie.

In most cases, simply setting up lights as they might appear in the final job will likely not generate the quality image you want any more than using an overhead light bulb in a photo studio will create acceptable lighting. Many of the cabinet design software packages you will compete with use this simple approach. If you take the time to properly set up lighting and control shadows, your images will be better, perhaps much better than shops you compete with that use simple ambient lighting. All the software, including ours use essentially the same licensed software to generate these images. By spending a little more time and effort, you can generate results that are noticeably better than your competition, regardless of what software they use.

The *Presentation View* works with lights you place in the workspace, realistically generating lighting effects, reflections and shadows that are a result of the lights and their placement.

The *Presentation View* provides certain tools. The ways these tools are used determine how rich, realistic and nice the final “shot” is.

As we said, the most simplistic approach is to place lights in the scene in the position they will exist in the real room and then simply generate the image. While this does work, a little more thought and effort can result in immensely better shots. If you have ever watched a photographer set up lighting for a shot or have seen how a play or movie set is carefully lighted, you will get an idea of the approach we recommend. We will use lights in much the same manner as the photographer, except they will be virtual lights created in our layout.

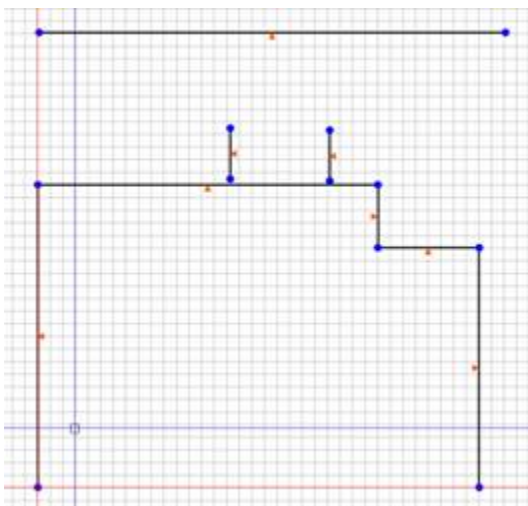

We will start by adding details such as items on the countertop, rugs on the floor and the like.

Use your imagination in this area. Many 3D STL images can be found on the web which can be imported into the *Display Part Editor*, textured and then added to your layout.

Here is a simple kitchen with some design details.

Next, we need to light and pose our room so that we can create an image using the *Presentation View*.

Next we will create a scenery wall on the outside so that it appears that we are looking out the window and door openings at a back yard.

Go back to the *Wall Editor* and create a wall 12' high across the back as shown. Also, create two walls that protrude straight back as shown. These will be used to block lights we place to simulate the sun shining through the windows and door. We will use three lights

for this so that the sunlight on the floor points in the same direction through all three openings. If we used a single light, unless we placed it a long distance away, the light would radiate out at different angles and not look natural.

We now need to add a scene to the back wall which will be viewed through the windows and door. If you are preparing the job for a client, you could use a digital photo of the actual scene outside his or her house for added impact.

We also added a light at the rear left corner to help light up the barn scene wall. Placing and adjusting these extra lights is a trial and error process. Generate the image and then add or adjust lights to get the effect you want.

We added two center lights at a height that will be seen in the final image and two more, toward the back which will not be seen. We will then adjust the intensity of the light coming from each of these to help light and highlight our room.

Notice how the two walls isolate the lights we will use for the sun so that each only shines through one opening but cannot shine through any other. We also adjusted the height of the lights so that they do not shine over the top of the back wall and into our room. The height is adjusted by

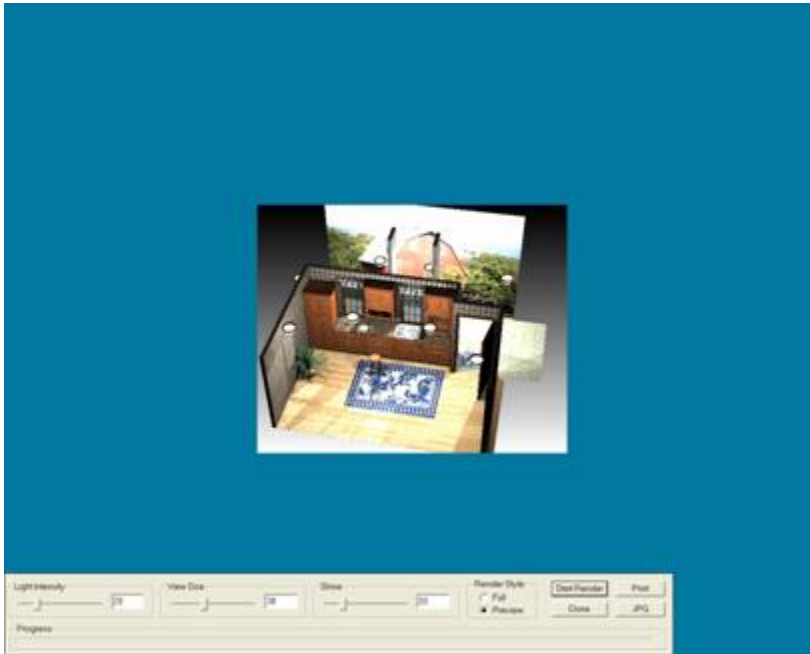

associating the light to a wall and then moving it up or down from an *Elevation View* of the wall.

Note that lights are added to the room in the *Detail Room* area and that only a few actual light fixtures are available. These are the only lights that the software recognizes as lights and the only items that will generate light in the scene. As you will see, if you don't need to show the actual fixture itself, you can place the light and then turn off lighting display in the *Show/Hide* menu selection. When you turn off lighting display, the fixtures do not display but they still are a light source, so you get the lighting effect from them even if you can't see them. This offers tremendous flexibility because, unlike a photo studio, you can place a light source in view of the camera without it showing.

We are now ready to move to the *Presentation View*. At the beginning, it is important to make sure the lights are not hidden and to orient the room from the Main display so that all the lights can be seen. We must see and be able to click on a light to adjust the light intensity coming from it.

Press the *Presentation View* button.

The scene will now render using the settings that were in effect when you last left the *Presentation View*.

There is a control panel at the lower portion of the display. It disappears unless the cursor is over the lower area. This control panel contains some simple controls that we will use to adjust our scene. These are very basic in the current version however, you can create rich powerful images with them. Many more software techniques can add even more capability and we plan to add much more

control in future releases.

The first thing you will notice is that it takes a long time to render an image. Since we will need to render the image many times while adjusting our scene, controls are provided that can speed this process.

The first of these controls is *View Size*. This controls how large the image of our room is. Since the process calculates the image one pixel at a time, the fewer pixels we need to process the faster the rendering time.

The second control is a selection of *Render Style*. Two selections are available, *Full* and *Preview*. *Full* renders every pixel creating the best possible image at each *View Size*.

*Preview* groups together pixels and renders these groups rather than individual pixels, providing an approximate image, but providing it much faster. The image from the *Preview* style is more than adequate for judging and adjusting the basic parameters.

The best approach at the beginning is to reduce the *View Size* and set *Render Style* to *Preview*. Once the image looks acceptable, go back to full *View Size* and set *Render Style* to *Full*.

There are two basic controls currently available, *Light Intensity* which only applies to lights, and *Shine* which applies to any item that has a texture, which is pretty much everything else except lights.

Basic settings are done by right clicking on the item and selecting *Adjust Shine* or *Adjust Light Intensity*. The current setting is also displayed. You can also re-render the scene by selecting *Render* from the menu.

This control gives you the ability to control the settings in increments of 10. If you need finer control than that, you will need to use the slide controls in the control panel at the lower left of the screen. Set the slide bar control for each setting, then right click on the item and select *Apply Dialog Settings*.

We will adjust our scene by first rotating it to approximately the orientation we will eventually want but moving out far enough that all lights are visible. We will then adjust the *Light Intensity* of each of the lights. Each light can be given a different *Light Intensity*. We might even need to exit the *Presentation View* to move some light around in the *Detail Room* area until we get the light and shadows we want. This can be done with a *View Size* of 25 - 40%. Don't forget you can move the lights up and down by associating them to a wall and switching to the *Elevation View* of that wall. Then use the arrow keys or hold *Shift* and use the right mouse button.

Once the lights are set, we will increase the *View Size* to 50-75% to better see the result and we will adjust the *Shine* or reflectivity of all the items.

Once these all look acceptable, we can change the *View Size* to 100% and change the *Render Style* to *Full*. We will then see a full display view of our layout with the best possible image quality. For some scenes, this can take quite awhile, especially on slower computers.

When setting the *Shine*, it is a good idea to add a *Shine* to pretty much everything. Items such as walls can be given a 1% *Shine*. This is because only after a *Shine* value is assigned to a texture does the true rendering power of the system start.

Start by setting the *Light Intensity*. We used 60% for the outside lights that simulate the sun. Then, click on each light you want to have that intensity. A red ping will occur when the current setting is applied to an item.

When setting *Shine* on a texture, you need only click on the texture one time and every item in the room that has that texture will be given the same *Shine*. If you click on a cabinet door, all doors as well as cabinets and anything else that uses the same texture as the door will be assigned the *Shine* value.

Once you adjust the *Light Intensity* and *Shine* settings, clicking on a texture assigns the current *Shine* value to that texture. Clicking on a light assigns the current *Light Intensity* to that light.

Here is the finished image of our farm kitchen.

The entire screen can now be captured as a JPG image by pressing the *JPG* button, setting the size image you want and specifying a directory and name. This process can take quite awhile, during which time the bottom control panel cannot be accessed. Simply wait until the control panel appears, signifying the process is complete. The image can also be sent to a color printer although, normally you will want to make further adjustments before you print as we will cover shortly.

Before you leave the *Presentation View* by pressing the *Done* button, reset the *View Size* and *Render Style* to reduce the initial rendering time when you again return. When you return to the *Presentation View*, the settings that were active when you left will be used. By resetting these you can keep for starting the next job with a full screen, *Full* quality rendering.

Once you have the image, you can open the *Image Control* area of the software and make adjustments to the image. You normally need to crop the image and normally it benefits from an increase in *Contrast* and *Saturation*. You can also adjust color balance, brightness and other parameters. Controls for these settings are accessed by selecting *Enhance Colors* from the *Image* menu selection at the top. Save the corrected file.

### ***Adding Cabinets and Items to a Custom Layout***

Adding cabinets to a room can be a bit confusing unless you know and understand how to use the available tools.

Items are placed in the layout in the *Detail Room* area reached by pressing the *Detail Room* button. In this area there are two “views”, an *Overhead View* and an *Elevation View* of a single wall. One of the things that can make this confusing is that certain items can be placed in the room from either the *Overhead* or *Elevation* view and others can only be placed from the *Elevation View*.

If you look to the upper left of the display in the *Detail Room* area you will see an area titled *Items to Install*. It contains a list of everything you can install in the room.

The first entry on this list is *Item*. If you select this you will see another list of various items starting with *Cabinets*. This entire list of items can be installed from either the overhead or the elevation view.

Under *Items to Install*, everything except the first selection (*Item*) can only be installed from the elevation view.

Let’s skip over *Item* and look at the remainder of the list then we will return and look at the various items that can be installed.

We discuss the *Door* and *Window* selections in the section titled “Placing Door and Window Images on a Wall”.

The next two, *Water Pipe* and *Water Drain* plus *Cut Out* and *Vent* are all utilities that are placed on a wall.

Early versions of the software envisioned these as utilities that the user could accurately place on walls, and then when the cabinets were placed in the room, the system could automatically add holes to the back of cabinets, or, shift the back of the cabinet forward to provide clearance for these utilities.

The ability to add the utilities to the wall remains, but the ability to automatically add clearance holes has not yet been developed.

Although the full functionality of these items is not complete, they are still a useful tool when laying out a room.

The pipes and drains display as copper colored pipes that stick straight out from the wall.

When you place a cabinet over these, the pipe sticks through the back of the cabinet. If you hide the doors, you can see the pipes inside the cabinet.

This can be quite useful when placing cabinets.

In the example shown, one pipe protrudes through the right side of the cabinet and another interferes with a shelf.

If you know about these problems before your layout is complete you may be able to shift the cabinet and/or move the shelf to avoid these kinds of problems during actual installation.

Of course, for this to be a truly useful tool, the walls and pipe locations must be accurately developed using precise measurements.

Available utilities include a *Generic Cutout* which is rectangular, a *Vent*, *Water Pipe* and *Water Drain*, which are all circular.

The size of each of these is established by right clicking and selecting *Sizable Utility Properties*.

From the dialog you can select the item you wish to size.

Note that there are two dimensions for *Vent*, *Water Pipe* and *Water Drain*, *Cutout Diameter* and *Pipe Diameter*.

This goes back to the original purpose of these tools which was to actually place holes in the cabinet parts to provide utility clearance.

The *Pipe Diameter* is the size of the actual pipe or vent.

The *Cutout Diameter* is the size of the hole you want to clear the pipe or vent.

The pipe is the only part that extends away from the wall. If you do not place a cabinet over it, the actual *Cutout Diameter* can also be seen drawn on the wall around the pipe.

This is one of those areas open for future enhancement should eCabinet Systems Members indicate that it is something they are interested in.

The *Light Switch* and *Electrical Outlet* are both for display purposes, although the *Light Switch* does have one function that can be used, sometimes to great amusement, during presentations. Later in the *Items* area we will talk about placing lights in the room. If lights are placed in the room, they can be turned on and off and one way of turning the lights on and off is by clicking on a light switch.

The final selection for placement on the elevation view of a wall is called *Snap Marker*.

This is also a carryover from earlier versions but can prove useful in some circumstances.

The *Snap Marker* is simply a marker, somewhat like a pencil mark on a wall used to locate cabinets during placement. For example, if you want a cabinet in a specific location, you can place a snap marker in that location and then use it to accurately locate the cabinet. It is called a *Snap Marker* because the cabinet (provided you are in one of the snap modes) will snap to the marker for placement. Once you snap a cabinet onto a *Snap Marker* and place the cabinet, the *Snap Marker* disappears.

When working with *Snap Markers* it appears that the marker has thickness, in its actual use it is a two dimensional plane with zero thickness.

If you set a *Snap Marker* at two feet and butt the edge of a cabinet against it, the edge of the cabinet will be located precisely at two feet.

Now, we will move to installing cabinets, appliances and other items. As we said, these can be installed from either the *Overhead* or the *Elevation View*. We will start with the *Overhead View*.

Loading the cabinet is easy, however, it is initially a wireframe image that moves around with the mouse. This wireframe is moved into position and when you click the cabinet is placed. There are several modes used to place the cabinet in position.

Basically the mode tells the system how to align the cabinet with adjoining cabinets. You move the cabinet close to where you want it and it snaps into place. This also keeps you from installing one cabinet meshed with another. That is, except for the *Freestyle Mode* which does let you mesh cabinets together and yes, there are reasons you might want to do this.

When cabinets are placed in a room, they are positioned at a specific height above the floor and then can be moved around the room at this height. Base cabinets are installed on the floor, detached toe cabinets are installed at the height of the detached toe base and upper cabinets are installed at a specified height above the floor.

This default mounting height is on the floor for base cabinets, is set in *Settings Preferences - Standard Dimensions* for the upper cabinet and is set in the *Cabinet/Assembly Editor - Construction Settings – Toe Kick* for a detached toe cabinet.

If these aren't acceptable, when you load a cabinet you can specify a mounting height by pressing the *Change Size* button. Once installed, mounting height can still be moved up or down should that be necessary.

Although we are working in the *Overhead View*, we can tilt the room front to back by using the *PageUp* and *PageDn* keys on the keyboard. This isn't quite as flexible as the *Main* page where the room can be both tilted and rotated but you will find this to be a useful tool when trying to precisely fit things together in three dimensions.

Note that items still move parallel to the floor, even when the room is tilted.

You can return the tilted room to the *Overhead View* by pressing the *Home* key.

Now, let's explore installing cabinets.

Select *Item* from the *Select Items to Install* list, check *Cabinets* and select a directory and cabinet to load. Note that you should click on the picture of the cabinet itself to select it and not the checkbox. The checkbox is used to identify cabinets that you want to delete. There is a *Delete Checked Items* button at the bottom of the dialog.

When you select a cabinet a blue bar appears and the size of the cabinet is displayed at the lower left.

This can be changed by clicking *Change Size*.

In addition to allowing us to change the size of the cabinet we can also change the height at which the cabinet is initially placed in the room.

If you have not developed your own library of cabinets yet, you can practice with the *Framed* cabinets in the *Standard Cabinets* directory. These are complete cabinets with slab doors.

Press *OK* and we have a wireframe of the cabinet.

As we move the mouse around, the wireframe follows. The way it acts in relation to other cabinets and the walls depends, however, on the *Insert Item Method* that is currently active.

Right click and select *Insert Item Method*.

The software supports four insert methods.

The first three *Insert Item Methods* all depict how a cabinet will react to other cabinets in the room.

- *Align to Back* aligns the new cabinet to the back of any existing cabinet it touches.
- *Align to Front* aligns the fronts.
- *Align to Center* aligns the centers.

These are all essentially the same if the cabinets are the same depth and only come into play if the two cabinets are different depth.

The fourth *Insert Item Method, Free Style* means you can put the cabinet anyplace you like regardless of what else might be in the way. The cabinet can be placed halfway through the wall or meshed with another cabinet. You are free to place it anyplace you want, hence the name *Free Style*.

There are actually practical reasons why you might want to mesh a cabinet with a wall or another cabinet.

For example, some cabinetmakers add a scribe to the outside of cabinet face frames which they trim during installation to precisely fit. The mesh ability allows you to design the cabinet box with the scribe and then mesh the portion that will be trimmed away into the wall.

As you work in this area you will soon see that measurements and fits are quite accurate.

If you create the room accurately, and build your cabinets accurately, the cabinets can be fit to a tolerance impossible to measure with a ruler.

Let's look at the behavior of the cabinet and the room when working in the *Detail Room* area.

The cabinet symbol will be the size of the actual cabinet as you move it around.

The background grid in this area works much like it does in other area we have covered.

The cabinet symbol has a V in the center that points to the front of the cabinet as shown.

The basic orientation of the cabinet changes as the cabinet comes in contact with wall or other cabinets.

When it contacts a wall, it turns its back to the wall and aligns with the wall.

It does the same thing when it contacts another cabinet.

If you are not in the *Free Style* mode, it snaps into alignment with other cabinets when it touches them.

Here we are working in the *Free Style* mode. You see a cabinet meshed with another cabinet and a wall. It has turned so that its front points away from the wall but is meshed with the wall.

If you continue to push it through the wall, it will reverse orientation when it reaches the other side so that it can be place on the other side.

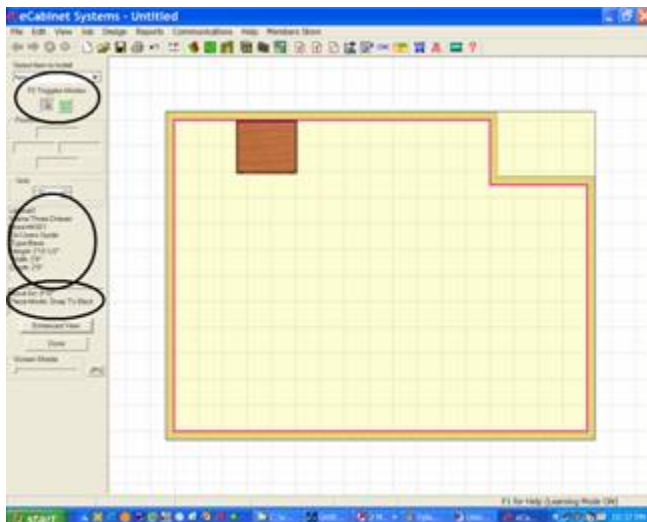

Cabinets can be placed on both sides of a wall.

The red line you see on the wall indicates the position of the initial *Wall Lines* you developed in the *Create Wall* area. This is also defined as the front side of the wall.

If you are in the *Free Style* mode, the cabinet will move smoothly through the wall, changing orientation about halfway through.

If you are in any of the other modes, it will stop at the wall as you move and then snap to the other side of the wall if you keep moving the mouse.

There are two modes when working in *Detail Room*, *Select/Move Mode* and *Insert Mode*.

*Insert Mode* is used to initially load and position cabinets and assemblies. The *Select/Move Mode* is used to select cabinets or items for any reason or to select and move these items after they have been initially placed.

The mode is selected using the icons at the upper left as shown.

They can also be selected by right clicking and selecting from the menu or they can be toggled using the F2 key.

The system automatically switches to the *Insert* mode when you select an item to install. If you want to select an item after installation for any reason, you must switch to the *Select/Move* mode.

If you are in the *Select/Move Mode* and pause the cursor over an installed cabinet, information about that cabinet is shown in an area to the left of the display.

Under this display information is another display showing the current *Move Increment*, *Pan Increment* and the active *Insert Item Method*.

This might be a good time to talk about cabinet numbers.

Each cabinet is given a number when placed in a room.

Cabinet numbers become important as the layout grows and reports are generated.

Cabinets are numbered consecutively as they are placed in the layout. The first cabinet is number one, the second number two, etc.

When a cabinet is deleted from the layout, all other cabinets with higher numbers are renumbered so that there is a complete, unbroken list of cabinet numbers.

This can be important if you run interim reports such, as *Cut Lists*, that rely on cabinet numbers. It is possible to run and print a report and then delete a cabinet and change the cabinet number of many of the cabinets in the report, making the report inaccurate.

Also, cabinet can be entered into the job in the *Batch Cabinets* area. Cabinets entered in *Batch Cabinets* are not numbered in the same sequence as those entered in *Custom Layout*.

Now back to installing cabinets. As we have already said, the cabinet will rotate to match a wall or other cabinets when installing it.

There are times, however, when you might want a cabinet at a specific angle and not necessarily have it match the wall or other cabinet.

This is accomplished using the *Modify Angle* function.

Right click and select *Modify Angle* to bring up the dialog shown.

Use this to rotate the cabinet to any angle.

You can also *Lock* the angle.

If you do not *Lock* the angle, it will maintain the angle you selected until it touches something else at which time it will take on the angle of the item it touched.

These characteristics can make developing an angled island or peninsula relatively easy.

Specify and lock an angle for one cabinet and install it.

Then, as other cabinets touch it, they automatically take on the correct angle.

Once placed in the room, other functions allow you to further adjust the angle.

Switch to the *Select/Move* mode and highlight a cabinet.

Right click and select *Edit Object* and then *Rotate Object*.

The dialog shown will appear.

Until now we have been rotating the cabinet around the Z Axis, as you might rotate it on the floor.

This dialog also allows you to also rotate the cabinet around the X and Y Axes. The cabinet could be laid on its side or back or turned upside down and hung from the ceiling.

This can actually be quite useful and becomes mandatory as the software begins to be used for designing items beyond cabinets.

rotate more than one item at a time.

You can highlight two or more cabinets, all the cabinets in an island for example, and then rotate them about their

combined center.

When more than one cabinet is highlighted, rotation is again restricted to rotation about the Z Axis.

This function is automatically used when you select *Modify Angle* from the *Right Click Menu* and more than one cabinet is highlighted.

If a single cabinet is highlighted full 3D rotation is available.

The final point we want to make about installing cabinets is the mounting height of cabinets.

When a cabinet is designated as *Upper*, it is automatically installed a fixed distance above the floor.

This distance is specified in the *Standard Dimensions* area of *Setting/Preferences*.

This area also specifies other parameters about how cabinets are placed with respect to walls, appliances or other cabinets.

You can get to *Standard Dimensions* by either going to *Settings/Preferences* and selecting the *Standard Dimension* button, or there is a direct link to *Standard Dimensions* from the *Right Click Menu*.

You might want to go through the various settings to become familiar with the areas that are controlled from here.

Regardless of the upper cabinet mounting height set in *Standard Dimensions* you can change this using the *Define Size* dialog when you are installing a cabinet.

You can also adjust the height after the cabinet has been placed.

Cabinets can also be installed from the *Elevation View*. The *Elevation View* is essentially a face on view of a single wall.

To work in the *Elevation View*, you must understand the concept of *Associations*. In essence, each wall has certain items that are “Associated” with it. When you look at an *Elevation View* of a wall, the wall and all items that are associated with it are shown, regardless of their location in the room. Anything not associated with the wall is not shown.

So how are things “Associated” to a wall?

Anything placed from an *Elevation View* of a wall is automatically associated to that wall. Also, cabinets placed in the *Overhead View* that are located against a wall are generally associated to that wall.

We say “generally” because sometimes if the cabinet is not exactly against the wall the system may not associate it. Corner cabinets, placed tightly in a corner are associated with both walls it touches.

The final way to associate or disassociate items to a wall is by highlighting the item, then right clicking on the wall and selecting *Associate to Wall* or *Disassociate From Wall* from the menu selections.

You might also note that items can be associated with either one or two different walls.

Some functions available from the overhead view are not available in the elevation view. *Duplicate Left*, *Duplicate Right* and *Auto Fill* will not work in the elevation view because they must detect adjacent walls which are not present in the elevation view.

To get an elevation view of a wall, from *Detail Room* place the cursor on the wall and press the right mouse button. From the menu select *Show Wall Elevation*.

From *Select Items to Install* select *Item*, then select a directory and a base cabinet. Click *OK*.

From the *Elevation View*, cabinets are automatically placed against the wall. You will note that they can be moved left to right, in fact, they can be moved right off the wall.

In the *Elevation View*, there is nothing to stop the cabinets at either end of the wall. In the *Overhead View*, we have the adjoining walls for location. These are not available in the *Elevation View* of a single wall.

In this case, you have three choices.

You can simply eyeball the placement getting it as close as possible visually.

If you need precise location, you can use *Snap Markers*.

From the *Select Items to Install* select *Snap Marker*.

Install a snap marker on the left end by roughly positioning it and clicking

Make sure you set the height of the marker above the floor so that the cabinet will contact it. Unless a cabinet actually touches a *Snap Marker* it cannot be used to locate it.

Don't worry about getting the position exactly perfect right now, just place it close to the left end of the wall.

Now, switch to the *Select/Move Mode*.

Highlight the *Snap Marker* by double clicking on it.

Now set the distance in the left dimension box to zero and press *Enter*.

You have now positioned the *Snap Marker* precisely at the edge of the wall. Press *Esc* to remove the highlight.

Here is what the wall now looks like (there are a couple of snap markers on the right side also).

Although the *Snap Marker* seems to have a width when we view it, in actual use it has a zero width. If we set it at zero, the edge of a cabinet touching it will be precisely at zero.

Now, switch back to the *Place Item Mode* and again select our cabinet. You will notice that when you move it over, the *Snap Marker* positions the cabinet correctly.

Note that when you install a cabinet against a *Snap Marker*, the *Snap Marker* disappears, its job being complete.

Another way of locating cabinets at the ends of the walls is to simply place them on the wall but away from the end. Then, switch to the *Select Move Mode*, highlight the cabinet, set the distance on that side to zero and press *Enter*. The cabinet will move to the end.

Note that the functions that automatically resize the cabinet for a smaller opening or the *Expand to Fill* command works from the *Elevation View*.

The height of a cabinet can be adjusted from the *Elevation View* by highlighting the cabinet. Then you can either type the new height above the floor in the position box to the

left or you can move it up or down using the up and down arrow keys. Each time the key is pressed, the cabinet moves the distance specified in the *Move Increment*.

Once items have been placed they can be further adjusted in several ways. We cover these adjustments in the section “Adjusting Installed Cabinets in Custom Layout”.

## ***Adding and Positioning Lighting***

Here is a fairly complex kitchen with a somewhat involved lighting arrangement. We have indicated the light intensity and shine on all major items to offer a starting point for your own layouts.

Here is the kitchen image that resulted from the above settings.

As indicated earlier, many more tools will become available in the future, however, with creative lighting and the techniques shown here, really rich images can be developed that are sure to help in marketing and selling your products.

As a final illustration, we will show you the lighting setups for several cabinet and furniture images along with the resulting images.

Working with a Custom Layout

## Using the Line Drawing Editor

### *Using the Line Drawing Editor*

The *Line Drawing Editor* is used to develop traditional line drawings of different aspects of the job. It offers computer assisted tools that make the process fairly quick and easy.

The process starts by sending a cabinet, group of cabinets or assembly from the *Cabinet/Assembly Editor* or sending a cabinet, group of cabinets, wall or entire room from *Custom Layout* to the *Line Drawing Editor*. There, items are rotated and positioned, copied and pasted between pages to obtain the basic drawing layout and then dimensions and notes are added.

The key ingredient in the *Line Drawing Editor* is a concept called a *Line Drawing Object*. A *Line Drawing Object* is essentially a three-dimensional line drawing, geometric representation of parts, cabinets, walls and complete custom layouts. The *Line Drawing Object* contains every bit of geometric data about the object.

Although the *Line Drawing Object* is a full three-dimensional representation of the object, a cabinet for example, you cannot access all the information at once. From a front view, it appears to be a two-dimensional line drawing of the cabinet front and all dimensions for the front area available. Data for the back is not available from the front view, however. To get data for the back, you need to rotate the *Line Drawing Object* of the cabinet until you have a back view. Now, the same object looks like a line drawing of the back of the cabinet. Turn it to the side and you have what appears to be a two-dimensional drawing of the side. Turn the *Line Drawing Object* to an angle and you have what appears to be an isometric drawing of the cabinet.

This simple concept is rather important because it forms the basis for the entire *Line Drawing Editor*.

To understand how this is used, let's look at a cabinet drawing. A common drawing is a front, side and top view of a cabinet. Typically this requires three two-dimensional line drawings, one for the front, one for the side and one for the top. In the *Line Drawing Editor* it requires three copies of the *Line Drawing Object* for the cabinet. One is turned to the front where it looks like a two-dimensional front view, one is turned to the top where it appears to be a two dimensional drawing of the top and the third is turned toward the side where it appears to be a two-dimensional view of the side.

It appears to be three separate line drawings but it is actually three identical three-dimensional *Line Drawing Objects* each turned a different direction.

The process for creating this is straightforward. The original *Line Drawing Object* of the cabinet is copied and pasted twice resulting in three complete copies of the cabinet. One

drawing is turned to the side, a second is turned to the top. The drawings are then moved to the proper position relative to each other and dimensions are added.

There are four types of *Line Drawing Objects*, *Parts*, *Cabinets*, *Walls* and *Rooms*. Some objects are contained inside others. For example let's consider a wall populated with cabinets. You can copy and paste the entire wall, but you can also copy and paste any of the cabinets on the wall. You can also copy and paste any individual part of any cabinet on the wall. In the same manner, you can copy any wall from a room, any cabinet from that wall and any part from that cabinet.

You should begin to see the incredible power and flexibility in this approach. The flexibility gets ever greater when you consider some of the options available when selecting *Line Drawing Objects* to send to the *Line Drawing Editor*.

There are two sources for *Line Drawing Objects*, the *Cabinet/Assembly Editor* and *Custom Layout*. The *Cabinet/Assembly Editor* sends the *Line Drawing Objects* that are highlighted. From *Custom Layout*, you can also select what you want to send. You can send the entire Job, a single wall with all associated items or, you can specifically select the items you want to send. When you do this they show up in the drawing in the correct dimensional relationship to each other.

You should recognize that when you send an entire layout as a *Line Drawing Object*, you are dealing with a lot of data so system response will be slower than if you work with a wall or a single cabinet. This means that you should try to work with the smallest object possible to achieve your goal, rather than send an entire layout and then copy a single cabinet to make a drawing.

Because of the high level of flexibility in selecting objects, you need to tell the system what type of object you are looking for. You do this by selecting one of the first four icons on the toolbar. They are *Cabinet*, *Part*, *Wall* and *Room*. If you select *Cabinet* complete cabinets highlight when you pass over them, if you select *Part* then individual cabinet parts highlight and can be selected. You cannot select a cabinet in the *Part* mode. You cannot select a part in the *Cabinet* mode. You can only select the type of object that is currently active, based on your toolbar selection.

One additional note, although the icon says *Room* it actually means the entire *Custom Layout*. If you have a layout that includes several rooms, they are all treated as a single room and are all selected when the *Room* icon is active.

You can highlight multiple objects by holding the *Ctrl* key while selecting. Therefore, if you want one room from a multi-room layout, you can switch to *Wall* select the walls that make up the room you want and send them. You now have a *Line Drawing Object* for the one room.

When you pass the cursor over an item, it will turn magenta color. This does not mean it is selected but does indicate what the system sees. If you click when a part is magenta it

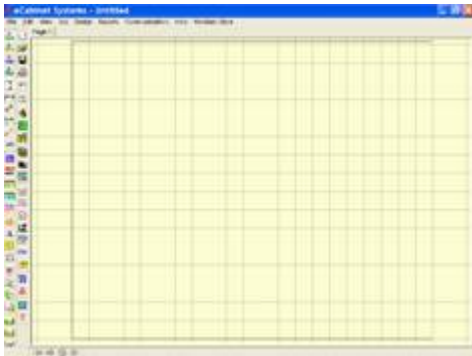

turns green which indicate that it is selected and can be copied, pasted, rotated and moved. If you click on a green highlighted part, it is de-selected.

You can move and rotate only parts that are independent *Line Drawing Objects*. If the selected object is part of another object, it cannot be moved or rotated independently. You cannot disassemble a *Line Drawing Object*. If a cabinet is part of a wall, you cannot move or rotate it by itself. You must copy it and paste it as an independent object. Then it can be moved and rotated. The same thing applies to parts on a cabinet. You cannot move a door away from a cabinet. You can, however, highlight the door, copy it and paste it somewhere else on the drawing or on another page where it can be moved and rotated at will.

This brings up another potential problem. What if the part you want to highlight is hidden by another part, or perhaps it is inside the cabinet. The system offers a *Hide* command that lets you hide a selected object so you can access objects behind it. When the object you want to hide is magenta, click on it. This will green highlight it. Right click to bring up the *Right Click Menu*. Select *Hide* and the object will disappear offering access to objects behind it.

The *Esc* key deselects everything.

The *Line Drawing Editor* supports multiple pages. Each page is a separate drawing. Objects can be copied and pasted between pages. Each time you send a *Line Drawing Object* to the *Line Drawing Editor* it is placed on a new page. You can also create a blank new page using the *Add Page* icon. You can also rename the pages to anything you want.

The page size is automatically set to the active page size of the current default printer on your computer. If you want a different page size, set the desired page size in the *File – Print* area. Select the printer or plotter you want to use and select the proper page size before accessing the *Line Drawing Editor*.

Once the printer and page size are properly set, let's set up the page area. Go to the *Line Drawing Editor*. There are two ways to access function here. You can use the various icons from the toolbar located across the top of the drawing page, just under the system toolbar. The same functions can also be accessed using the *Right Click Menu*.

By the way, the toolbars are standard windows toolbars so they can be relocated to the sides, bottom or anyplace else you like. An example of an alternate layout is shown here.

We will use the default layout in this guide.

Next, we will set the grid. Press the *Grid* icon and the dialog to the left appears. Grid dimensions are the actual measurements on the drawing page itself. You can turn the background grid on and off and, as with the other grids, there is a choice of three types of grid to display.

We will set the parameters to a half inch by half inch, solid line grid. Press *OK*

Next, we will select the font for the text on our drawing. There is a *Font* icon on the toolbar that can be used to access this function or you can right click and select *Font*.

The dialog to the left appears. We will use *Microsoft Sans Serif* in *Regular* form, 11 point size and black color. We will be able to change specific text on our drawing if needed by highlighting the text we want to change and either pressing the *Font* icon or using the *Right Click Menu* as we just did here. Changes are applied to new text and any text that is highlighted when the *OK* button is pressed.

The next area to define is called *Drafting Parameters*. It is accessed either through the icon at the top or by right clicking and selecting *Drafting Parameters*.

This area defines three functions. The first is the appearance of *Extension Lines*. *Extension Lines* are the lines that run from the object to the dimension line.

*Overrun* is how far the extension line extends past the dimension line. All measurements here are based on the printed page. If you set *Overrun* to  $\frac{1}{4}$ ", the line will

extend past the dimension line  $\frac{1}{4}$ " as measured on the final printed page.

The *Gap* specifies how far away from the node being measured before the extension line starts.

The next part of *Drafting Parameters* determines the line-to-line spacing of text. This affects text in each area including *Notes*, *Leaders* and *Tables*.

All the settings in *Drafting Parameters* will be used on new items placed on the drawing.

Changes to these parameters also affect any items that were highlighted when the change was made. If you highlight a dimension line and change the *Gap* or *Overrun*, the gap and overrun of the highlighted line will change. If you highlight existing text on the drawing and change the *Text Line Spacing* the line-to-line spacing of the highlighted text will change.

Changes do not affect existing items that are not highlighted.

The final area of *Drafting Parameters* concerns loading DXF files into the drawing and is covered in the section titled *Loading and Dimensioning DXF Drawing Files*.

The final item in setting up the drawing page is the *Edit Move Increment*. This is the distance items move, as measured on the page, when the arrow keys are used.

Select the *Edit Move Increment* icon to bring up the dialog. We will set it to .125 inch for this demonstration.

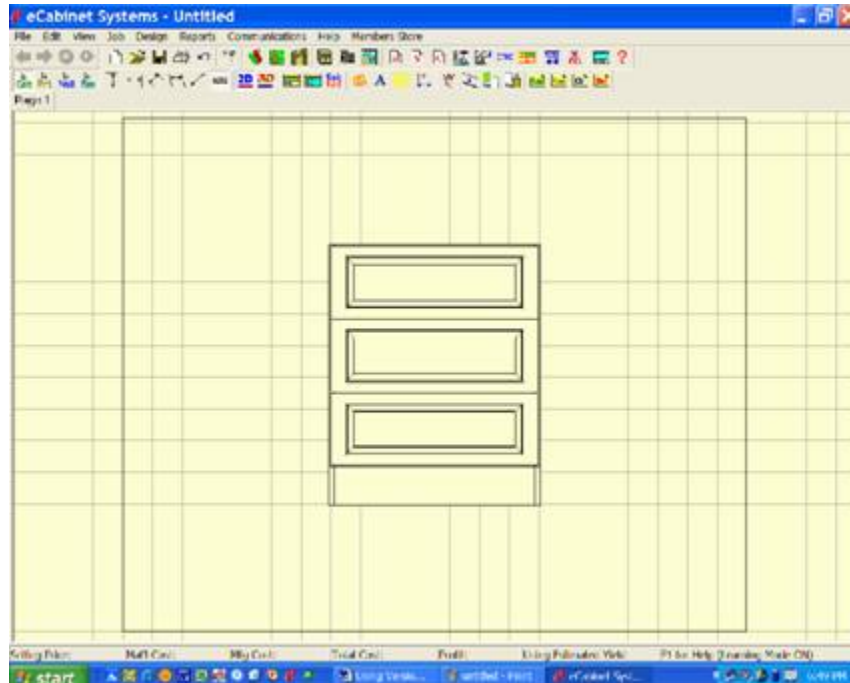

Now that the drawing area is set up, Let us create a standard front, side and top view of a three drawer base cabinet.

From the *Cabinet/Assembly Editor* we will load a base cabinet and then press the *Line Drawing Icon*.

From the dialog, select *Take Cabinet*.

This sends us to the *Line Drawing Editor* and takes the currently displayed cabinet with us.

The cabinet appears on a new page.

The cabinet appears too large and there is a temptation to zoom it down in size before you copy and paste it. Don't do it. When you copy and paste an image, the pasted image will be full size, regardless of the size of the image you copied. At that point it will be almost impossible to zoom the copies to the same scale as the original.

Instead, copy and paste all images you want even if they don't fit properly and then select and zoom down everything at once. This way you know that all the images are at the same scale.

Set the select mode to *Cabinet* by clicking the *Cab* icon on the toolbar or by right clicking and selecting *Select Mode – Cabinet*.

Move the cursor over the cabinet, when it turns magenta click on the cabinet to highlight it.

Copy it by holding the *Ctrl* key and pressing *C* on the keyboard.

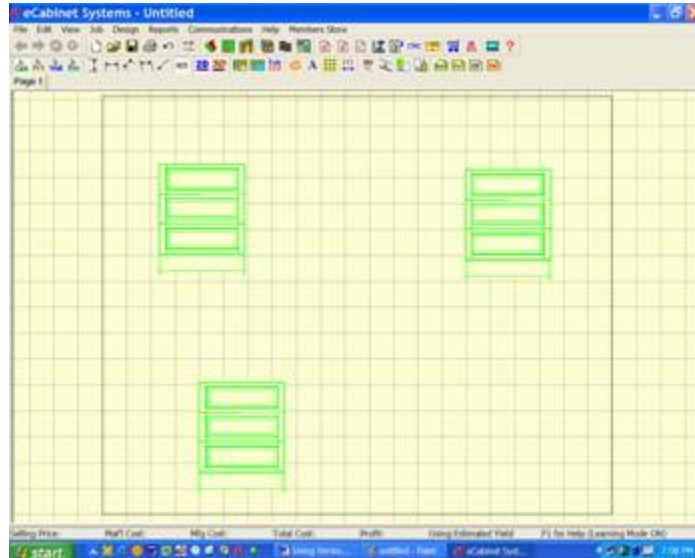

Now, you must move the original out of the way so you can paste a copy. While it is still highlighted, press and hold the *Shift* key and move the cabinet using the right mouse button.

Now paste a new copy by holding the *Ctrl* key and pressing *V*.

Press *Esc* to remove highlights from all items. Otherwise, if you try to move one you will move them all because they are all highlighted. You can now move the new copy out of the way so you can paste yet another copy.

You should now have three copies of the cabinet.

Highlight all three and zoom them down to a smaller size. Hold the *Shift* key and zoom using both mouse buttons. You now have three identical drawings of the front of the cabinet.

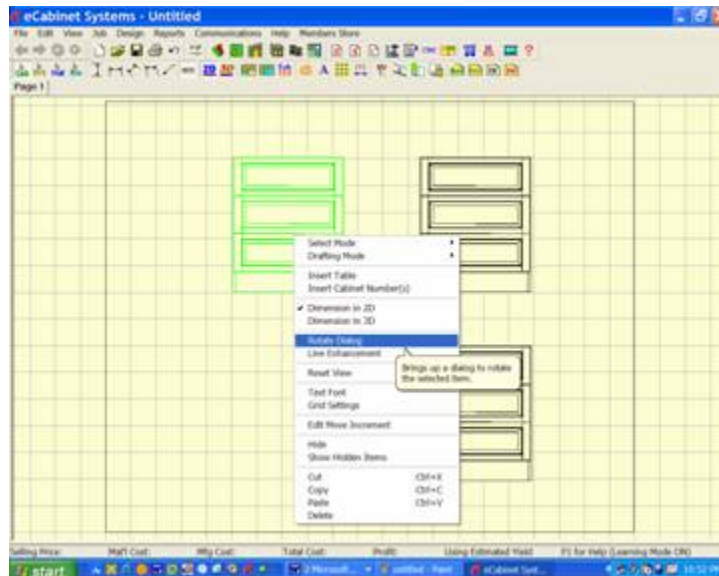

This might be a good time to note that you can highlight any items on the screen by clicking on them, or, if you click and hold the left mouse button you can pull a green rectangle over the items you want to highlight. Any item that the green rectangle touches is highlighted.

Press *Esc* to deselect everything.

Select and move one cabinet at a time by highlighting it, holding the *Shift* key and using the right mouse button, until they are positioned properly with respect to each other.

Now, highlight one of the cabinets. Then right click to bring up the *Right Click Menu*.

Select *Rotate Dialog* and a dialog screen appears that you can use to rotate the highlighted cabinet.

Turn one cabinet 90 degrees on the Y Axis and one cabinet 90 Degrees on the X Axis. The result is a standard front, side and top view drawing.

Now we will add dimensions to our drawing.

The *Line Drawing Objects* that make up our drawings are full geometric representations of the original items. This means that the relative position of everything on the object is known accurately. This means that you will not need to know any dimension number, but instead every dimension is developed by simply letting the system know what you want to measure.

We specify what we want to measure by clicking on nodes.

A node is the intersection of any two lines or the center of hole. Press *M* to see all available nodes on the page.

Because of the total flexibility, we can dimension almost anything. In two dimensions we can dimension the horizontal or vertical distance between two nodes. We can also dimension the diagonal distance between two nodes. We can also dimension in three dimensions. This is useful for dimensioning isometric orientations of the *Line Drawing Object*.

We will start by looking at two-dimensional (2D) dimensioning on our current drawing and then examine dimensioning in 3D.

Because of the variety of dimensions we can develop, we need to tell the system what kind of dimension we are trying to develop. We do this by setting a drafting mode.

If you look to the left of the drawing toolbar you will see a set of icon selections where we will indicate the drafting mode we want to use.

The first two specify we want the vertical or horizontal distance between the two nodes we select. These two modes are interconnected so that should you select two nodes whose dimension in the selected direction is zero, it automatically switches to the other mode. For example, should you set the *Vertical Mode* and then select two nodes, say the two top corners of a cabinet where the vertical dimension is zero, the system automatically switches to the *Horizontal Mode* and displays the width of the cabinet.

Since there is no practical reason to ever display a zero dimension between two points, this automatic switching saves a lot of time when developing horizontal and vertical dimensions.

Should you ever need to display a zero dimension, you can use the *Note* feature which will result in the same presentation. Now let's look at the creation of some dimensions.

Start by making certain that the *2D* icon is selected on the toolbar. Now move the cursor over the various nodes on the cabinet. When you pass the cursor over a node, it highlights as shown to the left.

Now, click on a node and move the cursor a dimension line attached to the node follows

node and away. A the cursor.

Highlight and click on a second node and a dynamic dimension line appears. Now, the dimension text follows the cursor. You move this into position and click again to anchor it.

You can leave the dimension between the extension lines or you can move it outside the lines as shown to the left.

This is useful when dimensioning nodes that are too close together to fit the dimension text as shown. Once the dimension text is placed, the actual text itself can be moved on a pivot line by highlighting the text as shown and, while holding the *Shift* key moving it using the left

mouse button.

Actually, every aspect of the dimension and text position, other than the nodes that define it, can be repositioned after it has been placed. There are two things you might want to change on a dimension, the position of the text or the position of the dimension line itself.

Here the 24" dimension text is highlighted. It can now be moved left and right along the dimension line.

Here the text and the dimension lines are both highlighted. Now, the distance of the dimension line from the cabinet as well as the position of the text can be adjusted.

You can delete a dimension by highlighting either the text or the text and lines and pressing *Delete*. Should you delete a dimension by mistake, the *Undo* icon or *Ctrl Z* restores it.

At times there are a lot of nodes concentrated in an area making it is difficult to select the exact node you want. When this occurs, you can easily zoom in and out during the dimensioning process.

Hold the *Ctrl* key and pull a rectangle. This time the rectangle is blue instead of red. When you release the mouse button, the screen zooms to the area defined by the

blue rectangle.

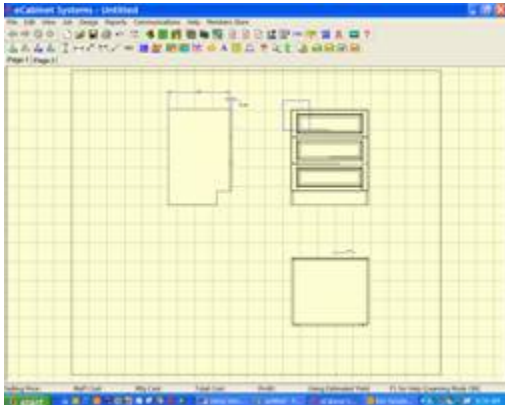

Here, the entire display has been zoomed to the area defined by the blue rectangle.

Press the *Home* key to return to a full view of the drawing.

After pressing *Home*, you can press the *End* key to return to this zoomed view. Now, let's look at defining a dimension using the zoom functions.

From this full view of the drawing page, we will place a dimension line showing the width of the top drawer in the drawer stack from the front view.

If you look carefully, you will see that there are a lot of nodes around each upper corner. It would be all but impossible to select the proper nodes without the zoom functions.

Notice that a blue zoom rectangle has been pulled over the upper left corner of the cabinet.

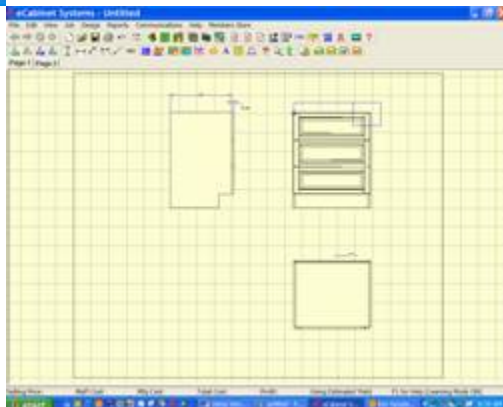

When the mouse button is released, it is easy to locate and click on the corner of the drawer front as shown.

Once the first point of the dimension been established, press *Home* and the returns to a full view of the drawing

From the full view and while the dimension line, pull a zoom over the right corner.

Again, when you release the mouse the view zooms to the area defined by the blue zoom rectangle.

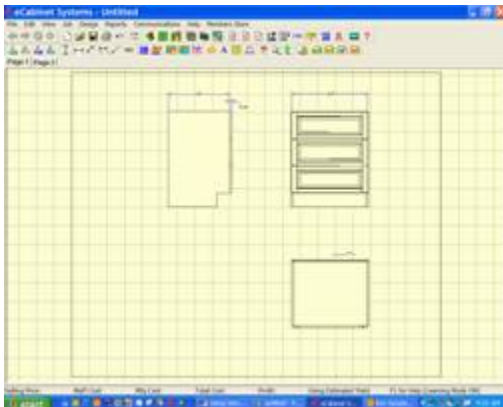

lines has display page.

dragging rectangle

button,

Again, it is easy to locate and click on the second corner of the drawer front.

Now the dimension line has been established, again press the *Home* key to zoom back to full view of the drawing page.

From the full view, you can locate and lock the dimension line and text.

This overall technique is critical to making the dimensioning process easy and accurate. It is actually fairly easy to do and should quickly become second nature with a little practice.

Let's take a closer look at the extension line and some special dimensioning techniques. Here is a front and side view of a cabinet.

We want to create extension lines between the cabinets and dimension the height.

To do this we need to reset our *Drafting Parameters*.

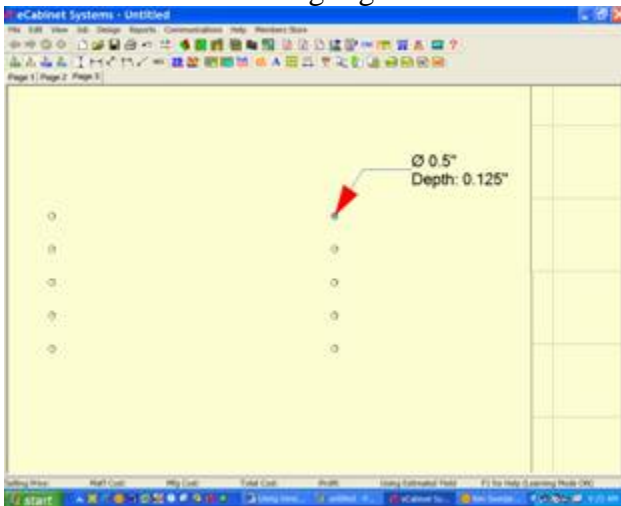

We will use these settings to place a dimension line between the cabinets.

Set the *Gap* to 1/8 inch and set the *Overrun* to 1.5 inch. Now place the dimension.

As you can see, we use the *Overrun* to extend the extension line from the dimension line to the cabinet on the right.

Changes to *Drafting Parameters* affect new dimensions that are placed as well as any dimensions that were highlighted when the change was made.

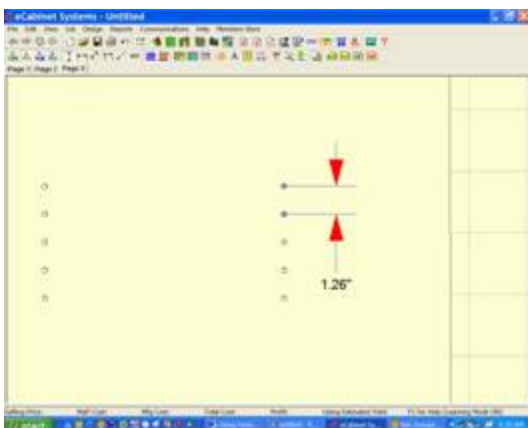

Next, we will examine how holes are dimensioned.

Shown here is a zoomed image of the inside surface of a cabinet side showing the holes for an adjustable shelf.

Notice that when you place the cursor over the center of a hole, it highlights like a node.

If you click on it and move away, the dimensions of the hole are displayed as

shown.

Again, you can position and anchor the text anyplace you want.

If instead of placing the text, you highlight another node, either another hole as shown here, or any other node, and then click on it, a standard dimension display is created between the nodes.

Now, let's look at how we create a dimension line between the row of holes and the edge of the part.

It is not really possible to dimension directly to the edge line since there are no nodes there.

Therefore, we set the Drafting Mode to *Horizontal* indicating that we will measure the horizontal distance between nodes.

Then, we find a node that is the same horizontal distance from the hole as the edge of the part.

In this example we are using the top right corner.

After clicking on the upper right corner, we pull the dimension line down creating an extension line that goes through the entire line of holes and provides the dimension display we want.

All of the dimensions we have placed so far have been either horizontal or vertical. It is also possible to dimension the diagonal distance between two nodes.

This requires that we select *Set* from the toolbar or select

*Aligned Dimensioning*  
*Aligned* from the *Right Click Menu*.

At this point, dimensioning works the same except that the dimension line maintains the same angle as the two nodes that were selected and the distance displayed is not the horizontal or vertical distance between the nodes but instead it is the diagonal distance between the nodes.

## ***Dimensioning in 3D***

All dimensioning until now has been measurements in two dimensions. This is specified by the 2D icon. The system also allows for three-dimensional dimensioning. The three-dimensional mode is entered by selecting the 3D icon from the toolbar.

When working in the three-dimensional mode, the distance measured between two nodes is the absolute three-dimensional diagonal distance in space. This is a powerful tool for certain applications but it can also be confusing in some circumstances and can lead to drawings whose dimensions appear to be wrong. We will cover this in detail after we demonstrate the use of 3D dimensioning.

Before we start, notice that the 2D toolbar icon is blue with a red underline. If you also look carefully you will see that the dimension lines while working in 2D are blue with red arrows, the same as the colors of the icon.

The 3D icon is red underlined in blue. You will soon see that dimension lines created in the 3D mode are red with blue arrows, the same as the 3D icon and opposite of the 2D dimensions. Therefore, when looking at a drawing you can instantly tell if a dimension was created in 2D or in 3D. This is **IMPORTANT!**

To demonstrate 3D dimensioning we copied the base cabinet and pasted it on a new page. We then highlighted it and holding the *Shift* key and using the left mouse button, we rotated it into this

isometric view.

We now select the 3D icon to put us in the 3D mode.

We will now introduce a new Drafting Mode called *Free Form*. In all the Drafting Modes so far, the extension lines from the node to the dimension line were essentially fixed. Their angle was set and could not be rotated. In the *Free Form* mode, the extension lines can be tilted to whatever angle is appropriate for proper presentation.

The examples to the left show the same dimension line moved about. This demonstrates the flexibility in positioning the dimension. The actual dimension is the distance in three-dimensional space between the two selected nodes.

Also, in selecting the nodes in 3D, the zoom feature works the same as in 2D.

flexibility and when

As you can see, 3D dimensioning offers a high level of is especially valuable dimensioning

isometric drawings.

This same capability, however, can cause problems if it is used to dimension two-dimensional drawings or *Line Drawing Objects* that are positioned in a standard orientation where it appears to be a two dimensional line drawing.

Here is a good example of how you can get into trouble using the 3D mode when dimensioning a 2D drawing.

Look at the actual dimension on each side of the cabinet. Both dimensions were created in the *Vertical* dimensioning mode and both appear to show the height of the cabinet.

One, however, shows the cabinet to be 34.50" high and the other shows the same cabinet to be 34.86" high.

They cannot both be correct, or can they?

Actually, they are both correct, they are just not measuring the same thing. The dimension line to the right, the blue line with red arrows, is a 2D line that measures the height from the floor to the top of the cabinet. The second line, the red line with blue arrows, actually measures the diagonal from the top of the cabinet to the bottom corner of the toe kick as shown. In the front view above, the angle of the dimension line cannot be seen and the viewer naturally misinterprets what the line is measuring. You must take great care when using 3D measuring to not create misleading dimensions like these.

The problem is even more confusing if you use 2D when dimensioning an isometric view.

Here we see three different dimensions between the same two nodes. All are correct but all do not measure the same thing.

The 29.083" dimension is the diagonal distance between the two nodes AS MEASURED ON THE XY PLANE.

The 28.594" dimension is the horizontal distance between

the two nodes AS MEASURED ON THE XY PLANE. Both of these lines are in blue, indicating that they are 2D measurements. Since the cabinet is not oriented so that you are measuring two dimensional distances, they appear to be incorrect when applied to the cabinet. These dimensions actually depends on the angle at which the object is rotated and have no practical use other than knowing how far the two nodes are apart on the page.

When a person sees a dimension like this between two points, they automatically make an assumption as to what the dimension is measuring, and normally they assume it is measuring a distance on the cabinet. Make sure that the dimension you present is measuring the thing people would normally assume you are measuring.

To avoid these problems, you should restrict the use of 3D measuring mode to isometric rotations and use 2D measurement only when working with a cabinet oriented in a standard 2D orientation (front, side, top, bottom, back). Another way to check for this is that ALL dimension lines should be RED for an isometric drawing and ALL dimension lines should be BLUE for a 2D drawing.

As you work with drawings you will find that a *Line Drawing Object* can be freely rotated until a dimension is added. Once a dimension is added, the object cannot be further rotated.

An object can be zoomed at any time, even after dimensions have been added. The text size for dimensions on an object does not change in relation to the drawing page as the object is zoomed. Whatever the text size specified, it will remain unchanged with respect to the drawing page as the size of the object increases or decreases. You must highlight the text and use *Font Control* if you need to change text size.

Once dimensioning is completed, there are some additional features that can be added to the drawing. The first of these is a *Leader*.

A *Leader* is a line with an arrow pointing to something and perhaps text on the other end describing what we are pointing to.

A *Leader* is placed by first selecting the *Insert Leader* icon from the toolbar or selecting *Leader* as the *Drafting Mode* from the *Right Click Menu*. Now, click where you want the tip of the leader arrow, pull out the leader line and click where you want the tail. Now, type the text you want and press *Enter*.

Once the leader has been placed, the position of the tail and text or the position of the entire leader can be adjusted.

To leave the arrow tip fixed and move the tail and text, click on the text to highlight it and which holding the *Shift* key, move the text using the left mouse button. To move the entire leader including the text, hold the *Shift* key and use the right mouse button.

Shown here is a typical assembly drawing for our cabinet using leaders to designate each part. Notice that the three drawer fronts use a single call letter. This was done by inserting the first two leaders without adding text and then adding the call letter for the third

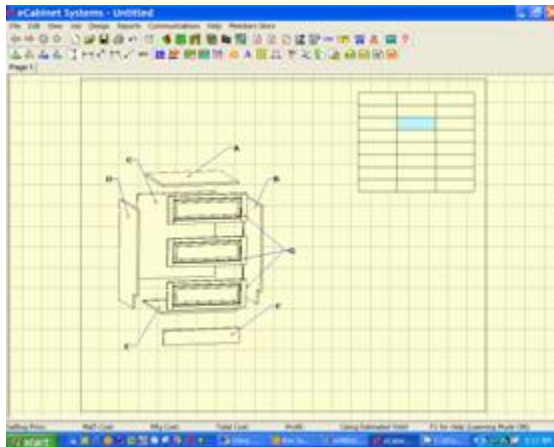

leader. You will need to highlight and reposition the text after it is placed because to the way text is initially placed.

We will use this drawing to demonstrate another feature, tables.

A drawing like this is often accompanied by a lined table listing a description of each part. We will now add such a table.

Click the *Insert Table* icon on the toolbar and the dialog to the right appears. We will create a table with three columns and eight rows. Press *OK*.

The table is inserted onto the drawing in the center. Hold the *Shift* key and using the right mouse button move the entire table to the upper right corner of the drawing as shown.

Next, we will move the vertical lines to the left as shown. As you move the cursor over the lines, they turn magenta, indicating that the system see them. If you click on a magenta line, it highlights in blue. The blue highlighted line can be moved by holding the *Shift* key and using the left mouse button.

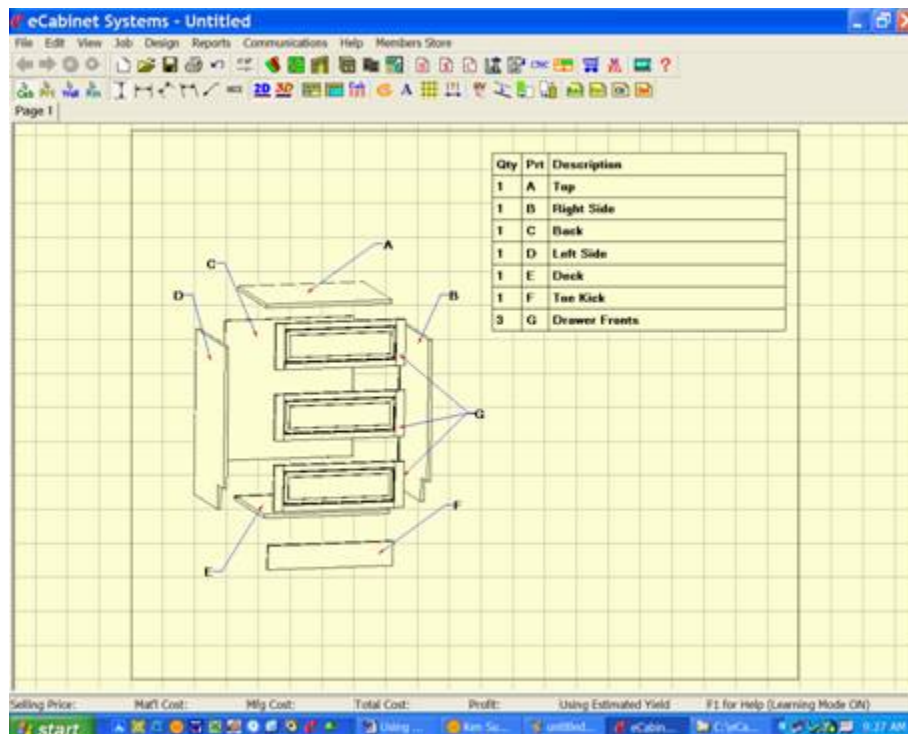

If more than one line is highlighted, they will move together, maintaining their position with respect to each other. Also, the outside lines defining the perimeter of the table can also be moved. To the left we have highlighted the three left vertical lines and moved them farther to the left, stretching the table.

Now we are ready to add text to the table. Text is added by holding the *Shift* key and clicking on a cell. The cell turns green and then you can type into it. Use the *Backspace* to erase text. Note that you can highlight more than one cell and any text typed appears in all highlighted cells as shown. Use the *Esc* key to remove highlights.

Here is the result so far.

To demonstrate other table features, let's create a title block at the lower right of our drawing. This time we will specify six columns each 1 ½ inches wide and 1 row, one inch high.

Here we see our table after it was moved to the lower right of the drawing. We will now adjust the vertical lines.

Here we have moved the lines and have highlighted the far right cell. We will split this cell into three horizontal cells. Using the *Split Cells* icon, we specify one column and three rows. This means that this cell will be subdivided into one column and three rows.

Here you can see the cell we just split. We now highlight the two left cells and will split these in half.

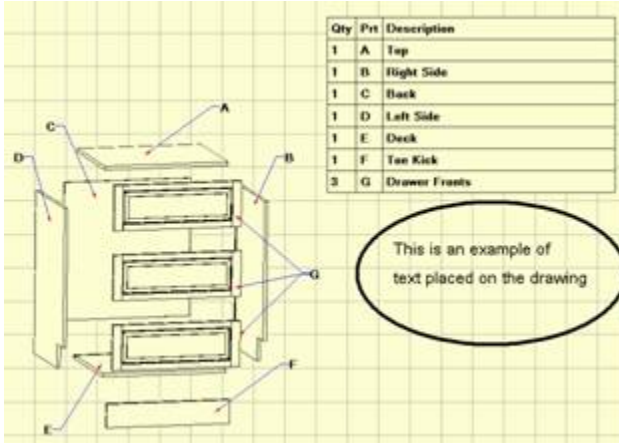

After splitting them in half, we moved the line down and split the right cell again. We have now completed our title block.

We have added titles to some of the cells but have not added specific information about this particular drawing such as drawing numbers, etc. We can now copy and paste this title block to other drawing pages in this job. To copy, highlight any cell and press *Ctrl C*.

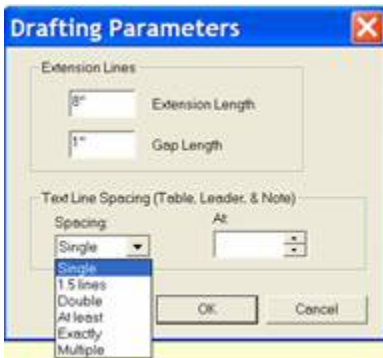

Go to the next page and click anyplace on the page then press *Ctrl V*. The title block will be pasted in the same location on that drawing page as on the original. Any table can be copied and pasted in this manner.

You can also place text on the drawing in any location. Set the font you want and then press the *Note* icon. Click on the drawing where you want the text located and type the text you want.

Once placed, text can be highlighted and moved as needed.

Also, you can copy and paste text from other applications using the Windows copy and paste commands (*Ctrl C* to copy and *Ctrl V* to paste).

One final area to cover for text placement, which applies everywhere text is placed, is *Text Line Spacing* in *Drafting Parameters*. Again, *Drafting Parameters* are accessed through an icon on the toolbar.

This offers a familiar control over the line to line text spacing. As with other *Drafting Parameters*, changes here affect any new text added as well as being applied to any text that was highlighted when the change was made.

The next area we will cover in the *Line Drawing Editor* concerns the density of the drawings lines. Because of the technique used to create the image, sometimes lines are broken and not solid as shown in the highlighted area to the left.

It is also possible that interior lines defining shelves or other interior components could bleed through to the front surface.

Because of this effect, which can vary from system to system, an adjustment has been provided. This adjustment is called *Line Enhance* and is accessed through an icon on the *Line Drawing* toolbar.

Increasing the number makes the lines more dense. Decreasing the number makes the lines less dense and will eliminate bleed through if it exists.

You need to find the best balance for your applications. Here, we changed the setting from 0 above, which resulted in a broken line, to 3, which closed the line and made it solid. 3 is the system default unless you change it. These changes are on a page by page basis so if you change it for this page, the change will not be applied to any other drawing pages. Each drawing page must be adjusted independently.

The final area we will cover in the *Line Drawing Editor* is *Cabinet Numbers*. When cabinets are placed in a *Custom Layout* each is given a number. This cabinet number is used to identify the cabinet in all areas of the software. If you run a *Cut List*, *Buy List* or other reports, you will find cabinets identified by their cabinet number. These cabinet numbers are also associated with the *Line Drawing Object* of the cabinet in the *Line Drawing Editor*.

To display the cabinet numbers, click on the *Cabinet Number* icon in the *Line Drawing Editor* toolbar. Cabinet numbers, in the current font and text size, are placed over each cabinet.

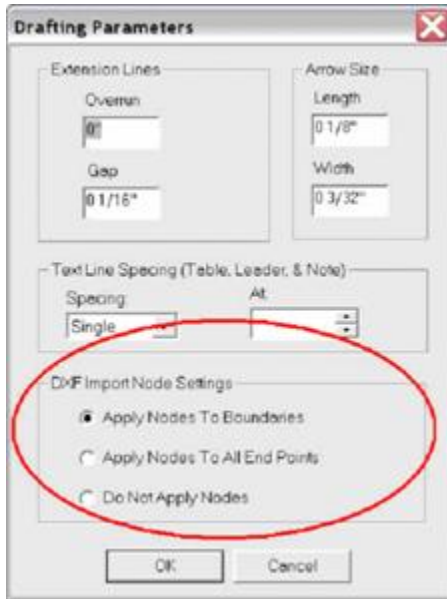

Once placed, these numbers can be highlighted and moved as needed. Make sure you don't move them over another cabinet. You can press the *Cabinet Number* icon at any time and return the cabinet numbers to their initial default locations over the cabinets. This completes our overview of the *Line Drawing Editor*. As you have seen it offers a powerful tool for creating almost any type of drawings needed.

## ***Loading and Dimensioning DXF Drawing Files***

In addition to *Line Drawing Objects*, you can also load DXF drawing files into the *Line Drawing Editor*. This allows drawings or objects that have been generated by an outside CAD system to be added to a drawing. In addition, these can be dimensioned using the *Line Drawing Editor* dimensioning tools.

To load a DXF file onto the current page, right click and select *Load DXF*. The drawing loaded from the DXF file is treated as a Part and can be copy/pasted, dimensioned, moved, rotated, or scaled, in the same manner as a part.

DXF drawings loaded into the *Line Drawing Editor* can be dimensioned but, in order to dimension using the *Line Drawing Editor* dimensioning tools, the object needs nodes that can be selected. Standard DXF files do not contain these nodes so nodes must be added when the DXF drawing is loaded.

This is done automatically based on settings in the *Drafting Parameters* area. To access *Drafting Parameters*, right click and select *Drafting Parameters*. *Node Settings* should be set based on what you plan to do with the DXF file drawing.

If you do not plan to dimension the drawing, select *Do Not Apply Nodes*.

The more selection nodes there are, the slower the system operates so we need to select how nodes are applied with this in mind.

There is a bounding box that surrounds the box. This bounding box can be selected *Apply* applied to

the entire drawing. This bounding box is used to generate nodes. If you select *Apply Nodes To Boundaries* nodes are placed at the four corners of the bounding box, the center of each edge of the box and the center of the box as shown on the top drawing to the right.

If you require more detailed node placement, select *Apply Nodes To All End Points* and each end point in the DXF drawing is assigned a node as shown on the bottom drawing to the right. Some DXF drawings have hundreds or even thousands of these end points, in which case this selection may noticeably slow the system.

Once the DXF file is loaded, these nodes can be used to dimension the drawing in the same manner as nodes on *Line Drawing Objects*.

## Using the Display Part Editor

The *Display Part Editor* is an area of the software that offers a powerful graphics tools used to add color and texture to three-dimensional objects which can then be used in the *Cabinet/Assembly Editor* or in *Custom Layout*.

This process starts with a three-dimensional graphics file that is generated by a third-party software program. The file must be in the *.stl* or *.hsf* file format. Many three-dimensional CAD packages can output *.stl* files. In addition, several web sites provide *.stl* files for download. Some of these sites charge for downloads and others are free.

The eCabinet Systems web site also has an area where Members post three-dimensional files. Some of these are *.stl* and others are *.hsf*, already fully rendered and ready to use.

In addition, in the directory *ecabinets/sample\_STLs* you will find some *.stl* files that you can process through the *Display Part Editor*.

Finally, any part in the *Cabinet/Assembly Editor* or *Custom Layout* can be exported in the *.hsf* format and loaded into the *Display Part Editor*. These can then be textured and saved as *.hsf* where they can then be used as *Display Objects* in the *Cabinet/Assembly Editor* or *Custom Layout*.

You can export an item, display part or part of a cabinet in the *.stl* format from the *Cabinet/Assembly Editor* and then load it into the *Display Part Editor* where appearance and texture can be added or adjusted. This is especially important for some parts that are modified in the *Part Editor*. Cabinet parts automatically receive a texture using standard settings. When a part is modified, many times the texture settings do not produce an acceptable appearance. Exporting these parts and then texturing them using the *Display Part Editor* is a way to improve the appearance.

There is a downside to this, however. When a cabinet part is exported and textured in the *Display Part Editor*, it is saved as an *.hsf* file. It is then loaded back into the *Cabinet/Assembly Editor* as a display part. At this point it is no longer a cabinet part, it is a display part. It will not be included with the cabinet parts in the Cut List and will not be nested with other cabinet parts.

We will describe the operation of this area by creating some examples. You can work along with these examples using your system.

Bring up the *Display Part Editor* using the icon located in the toolbar at the top.

We will use one of the *.stl* files from the *sample\_STLs* directory for our example here. We will show how the item changes appearance as various settings are adjusted.

Controls available in the *Display Part Editor* are shown to the left.

Start by pressing the *Load STL/HSF* button. We will select the file *Sample\_Plate1.STL*.

The work area in the *Display Part Editor* is oriented the same as the *Overhead* view in *Custom Layout*. When the image first loads, it is oriented as it would appear in the *Overhead* view in a *Custom Layout* and is pure black. It can be manipulated using the standard mouse controls and after rotating looks something like this.

We will start by changing color. The Red, Green and Blue at the top control the color of the item. Each can be adjusted from zero to 255. Change the Red to 255 and you get the following:

If you look at the image carefully, you will see that it does not look particularly smooth but has ridges and color variations.

If you look at the controls you will see that *Flat* is checked as the *Render Mode*. Change this to *Gouraud*.

This result is much smoother and more realistic. This might be just the opposite for a flatter part. As a general rule, try both *Flat* and *Gouraud* and use the setting that gives the best overall appearance.

Change the Blue Setting from zero to 255. The plate is now a purple or magenta color.

Changing the Green setting to 255 results in a pure white color. 0,0,0 is a black, 255,255,255 is pure white. Numbers between these can create 24 million different colors.

In trying to determine a color, you can turn to a typical color definition dialog. These can be found in a variety of formats in a lot of different software. You can access one right from this area by pressing the *Select Image* button and then selecting *Add Custom Solid Color* and then selecting *Define Custom Color>>*. Work with the mouse to develop the color you want and then copy the Red, Green and Blue settings for that color into the *Display Part Editor*.

We have changed the color to a blue and will now show you how the *Gloss* and *Specular* controls function.

Here is the plate with both *Gloss* and *Specular* set to minimum. It appears flat with few highlights.

Increasing three-

the *Specular* increases the effect of the color and adds a dimensional aspect to the image.

Now, increasing the *Gloss* makes the surface shinier. *Gloss* and *Specular* interact in determining the appearance and you will need to experiment with the settings to get the appearance you actually want.

Checking *Transmission On* makes the image transparent, like it was made of glass.

The darker and more intense the color, the more opaque the appearance. A pure white color results in an almost perfectly clear glass look.

Both *Gloss* and *Specular* still function with *Transmission On*. High *Specular* and *Gloss* result in a clear glass look with a shiny surface. Low *Gloss* and *Specular* result in a product that is transparent but with a flat less reflective surface.

The *Gloss* control makes the surface shiny or reflective. In the real world, as a surface becomes more reflective, it begins to reflect its environment. A mirror is a good example of this.

To simulate this, the *Display Part Editor* uses a selection called *Environmental Mapping*. Before this works, you must select an image to reflect. This is done by pressing the *Select Image* button. Within the selections is a directory called *Reflections*. This contains images that result in various shiny appearances. These images look a little strange but do create some really nice appearances.

As a general rule, the sharper and more abrupt the contrast between colors the more reflective the surface will appear. As the boundary between colors becomes more gradual, the surface it reflects from will appear less reflective and shiny.

The *Mirror* control adjusts the brightness of the reflected image, changing the appearance. To the left it becomes less shiny and uses the color set above. As it is moved to the right, it becomes more reflective and takes on more of the color of the image being reflected. You may want to try several of these images and work with the *Mirror* control to get a feel for the effects you get. Following are some composite images showing the image used and the effect on our plate.

Another way to use an image is to map the image to the surface of the part. Select an image and then select *Texture Mapping*. There are two additional controls that affect how the selected image or texture is mapped to the surface of the object. The first is *Texture Scale* and it determines the size of the texture image with respect to the size of the object itself. Increasing the number increases the size of the texture image. The second control rotates the image with respect to the object. Using these is a trial and error process. Rotate the image to achieve the best overall appearance. Here are some images mapped to our plate.

As you can see, the variety of appearances possible is virtually unlimited. You can even use flowered wallpaper to create flower patterns on the plate.

Using the tools just shown, a single object can be colored and textured and given almost any surface appearance. Some items, however, are comprised of two or more components each with a different appearance. It is possible to duplicate these items by loading more than one *.stl* file and then locating and texturing them individually. They can then be saved as a single *.hsf* display part.

To demonstrate this we will load another *.stl* file from the same directory. This time we will use a glass represented by the file *sample\_glass1.stl*. Here you see the original plate and the glass we just loaded. You will notice that the glass is oriented upside down and under the plate. This most likely means that the coordinate system that the glass was created in is oriented differently than the coordinate system that the plate was created in. This is a common occurrence, especially when using files from different sources. The *Display Part Editor* provides controls that let you invert various axes as needed to match coordinate systems.

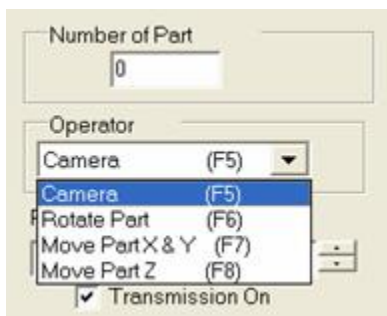

It is not absolutely necessary to match coordinate systems, however, if you don't, objects will rotate and move in the wrong direction when you try to manipulate them. In this

case, we will reverse all the axes since not only is the Z axis backward but the glass moves in the wrong direction when you try to move it.

The buttons under *Invert Part* invert the various axes by depressing them. As you see, the glass has moved to the top side of the plate. We have made the plate transparent to show that it is not, however sitting on the plate but is suspended above it.

It is possible to move or rotate the plate and, in fact it is possible to modify the appearance of either of the two objects individually. Notice at the top that the *Number of Part* display now reads 0. This is the first part loaded, in this case the plate. Any changes made will apply to just the plate. To select the glass, RIGHT click on it and the *Number of Part* will read 1. You can now make changes to the glass. Moving parts, however, gets a little more involved.

If you look at the top of the control column you will see an area called *Operator*. In this area are four selections. The selection determines what moves when you use the mouse controls.

The first is called *Camera*. When this is selected, everything moves. It is called *Camera* because it is very much like having a fixed scene and simply moving the camera to view the fixed scene from different directions and orientations. In *Camera*, the scene doesn't change, only your view of the scene changes.

This is actually fairly important because the orientation of the object with respect to the real world, the scene, is the orientation the object will be in when it is placed in a room. If you actually rotated the glass on its side in the real world, when you placed it in a room it would be lying on its side.

The next three selections actually move or re-orient the active object. If you select *Rotate Part*, the active part will rotate with respect to all other parts and with respect to the real world. To the left you can see what happens when we use the *Rotate Part* function on the glass, which is part 1. You need to hold down the *Shift* key while using the right mouse button to rotate or move a part.

Here we see our plate and glass positioned next to each other and at a common height as it might be used as a place setting. Doing this required switching between *Move Part X&Y* and *Move Part Z* to position the glass next to the plate and adjust the height. It also required us to switch back to the *Camera* view several times to evaluate how we were doing. Take some time and play with the controls to get familiar with the various operators.

Once the object or objects are complete, you can save them as an *.hsf* file that can be used by the program. You can specify a directory name and file name. They are saved with your directory becoming a sub-directory of the *ecabinets* directory because that is where the system looks when placing a *Display Object*. You can also input a cost for this item and indicate that you want it added to the *Cut List*. Then, when you add the object to a *Job*, it is also added to the *Cut List* and its cost is added to *Material Cost*.

Developing a pleasing appearance for an object can take some time and effort so, once you develop one that you like, you can save the appearance settings by pressing the *Appearance Settings* button. From this dialog you can save the current setting, load previously saved settings or delete settings you may have saved in the past. There are several saved appearances already available in this area that you might want to experiment with.

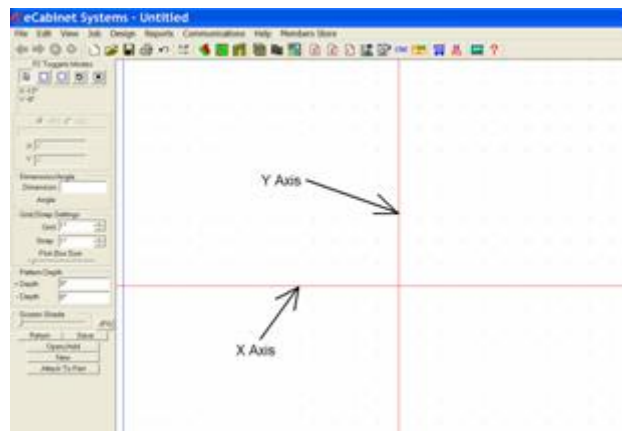

## Using the Hardware Hole Editor

The *Hardware Hole Editor* is an area of the software used to create a mounting hole pattern that is then associated with a piece of hardware. When that hardware is used on a cabinet, the hole pattern is automatically added to the appropriate parts.

Most hardware offered in the eCabinet Systems program already has a hole pattern associated with it. If that hole pattern is acceptable, you need do nothing else. If not, this editor can be used to either create a new pattern or modify the one that currently exists.

The basic approach is to define a geometric hole pattern, save the pattern and then associate it with one or more components. When these components are used on a cabinet, the associated hole pattern is automatically added to the appropriate cabinet parts.

If your parts are to be processed on a CNC router these hole definitions are important because they will be machined into each component. This saves substantial time, allowing hardware components to be mounted to cabinet panels prior to assembly.

The key to using this area is understanding the basic concept behind the layout of the hardware hole patterns.

The single most important point to understand is that the way a hole pattern is defined is different for different types of hardware. The way the pattern is defined depends on the type of hardware the pattern is for. Although the workspace is the same, the procedure is different for different types of hardware. Once you understand this, creating the pattern is fairly easy.

The workspace is a CAD type drawing area bisected by an X and Y Axis. The X and Y Axes are a key to understanding how to develop the hole pattern. The significance changes for the X and Y Axis, based on the type of hardware that the hole pattern is for. For example, for a door hinge, the Y Axis separates holes that are drilled into the cabinet

side (those to the right of the Y Axis) from the holes that are drilled in the back of the door (holes to the left of the Y axis). The same Y Axis functions differently when used to define holes for KD/RTA fasteners. Holes to the right of the Y Axis are cut into the edge of one panel and holes to the left of the Y Axis are machined into the face of the mating panel. The *Area Overview* for this area details the way hole patterns must be located for each type of hardware. You should print out this information and the diagrams and use these for developing hole patterns.

The X Axis is also significant because it defines how the hole pattern is located along the edge. For example, when specifying hinge location for a door, you specify a distance that the hinge is located from the door edge. What you are really specifying is the location of the X Axis in the hole pattern for the hinge. If you locate the holes so the X Axis is in the center of the hinge, you are then locating the center of the hinge.

Understanding *Depth* is also important. As a general rule, a *Minus* depth is cut into the cabinet component. The dimension is measured from the surface of the part, so a minus ½ inch depth is drilled one half inch into the part.

*Plus* depth is primarily used for locating drill holes into a drawer body. On a drawer slide, a minus ½ inch depth and a plus ¼ inch depth for a single location will drill a hole ½ inch deep into the side of the cabinet and will drill a second hole in the same location ¼ inch deep into the drawer body.

Note that even though the drawer body and cabinet side are separated by the thickness of the drawer slide, the hole depth for both parts is measured from the surface of the part and not from a common center point, even though that is how they are displayed.

To demonstrate, we will develop a hole pattern for a hinge and drawer slide. The process for other components is similar.

Above are diagrams similar to those found in hardware catalogs that define the required hole pattern for a component. The diagram to the left is a machining pattern required to attach the hinge to the door and the pattern to the right shows the mounting holes that must be drilled into the cabinet side.

For the particular hinge and overlay we are using, the *Tab* dimension above is 3mm.

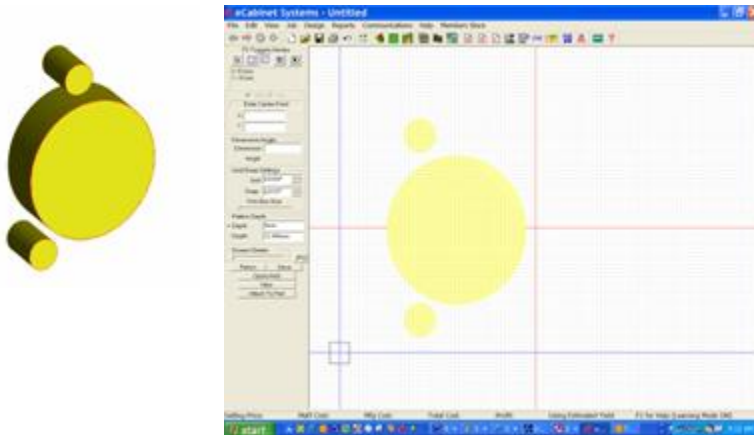

Start by setting up the editor for this task. Since the dimensions in our drawing are in millimeters, go to *Settings/Preferences* and change *Dimension Display* to *Metric*.

Next, since some dimensions are in half millimeters, we will set the *Grid* to 1mm and the *Snap* to .5mm. Next, use the plus key to zoom to a comfortable working height.

Start by defining the 35mm hole. The right hand vertical edge of the door is the Y Axis on the drawing. The center of the hole is half of 35, or 17.5mm plus the *Tab* which is 3mm for a total of 20.5mm.

Set the hole depth, in this case -12.5mm. Then locate the three holes. The result looks like this.

You can view the pattern we just developed in 3D by pressing the *View* button and using the mouse controls to move and rotate it as shown to the right.

Now let's place the holes for the mounting plate. These holes are placed to the right of the Y Axis. Leave the hole depth at 12.5mm and locate two holes 37mm from the edge and 32mm apart. In 3D, the final hole pattern looks like this.

Now that this hole pattern is complete, we save it under a name. Then we will associate it to the actual hinge and mounting plate we plan to use. Press *Attach to Part* and select the type of part and the vendor. Then, select the actual piece and associate it to the hole pattern.

Note that if you are using a hinge and separate mounting plate, you have the choice of creating a hole pattern for the hinge and mounting plate combination and associating it to the hinge or, creating a separate pattern for the hinge and the mounting plate and associating one pattern to each component. If you always use a particular combination you can use a single pattern. If you mix hinges and mounting plates you should probably create a separate pattern for each.

Next, we will develop a mounting hole pattern for a drawer slide. Start with a diagram of the slide that shows mounting hole locations for both the cabinet side as well as the drawer box.

This is a little different than the hinge since all holes are located to the right of the Y Axis.

Holes with a *Minus* depth are put into the cabinet side and holes with a *Plus* depth are drilled into the drawer box.

We will start by locating the holes in the cabinet side. Set the minus hole depth and locate the required holes. In 3D, the resulting pattern looks like this.

Now we are going to define holes in the same location but this time they will be in the *Plus* direction and only half the depth. We have also added two additional holes in the positive direction for illustration. The 3D view of these is:

You will notice a small red area on each hole. This separates the holes that extend above, which are the ones that go into the drawer box, from the holes that extend downward, which go into the cabinet side. In actual operation the holes that extend in both directions can be placed at one time by specifying both a *Plus* and a *Minus* direction.

This gives you an overview of the operation of this area. Other types of hardware use the X and Y Axes in somewhat different manners, but the basic principles are the same.

## Using the Shape Manager

The primary purpose of the *Shape Manager* is to create shapes or profiles. These shapes or profiles can then be used to create profile tools which can then be used to cut a profile on a cabinet component in the *Part Editor*. In future releases, the *Shape Manager* will be expanded to develop and save shapes, such as the shape of a cut-out for a sink, which can then be imported into the *Part Editor* and added to a part.

Tools created by the *Shape Manager* are a bit different than what you are used to. You can, of course, create symmetrical tools that will then function like a router bit. In addition, you can create non-symmetrical tools, that is tools that are different on one side than the other or even tools that only have one side.

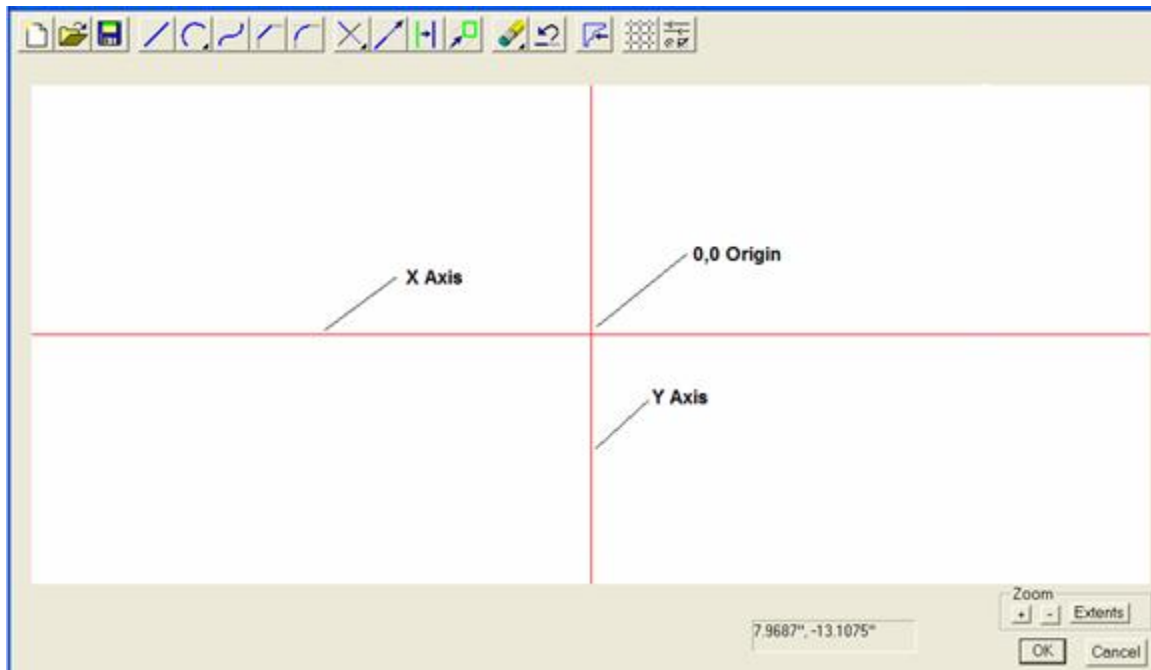

The tool shape you create in the *Shape Manager* is swept along a path defined in the *Part Editor*. The tool does not rotate, it just moves along the path sweeping out the shape, almost magically. Obviously since the tool is not symmetrical, it will create a different result if it is swept along a path in one direction rather than the other. This means that when using non-symmetrical tool, you must pay special attention to the direction you are cutting.

A good way to visualize the way a tool will cut is to imagine you are standing behind the tool shape and it is cutting while moving away from you. This is also a good way to visualize *Right* and *Left* directions for tool compensation and other adjustments. We will cover those shortly.

You might wonder whether you could ever cut a profile made by a non-symmetrical tool, especially a groove where the profile on one side of the groove is different than the groove on the other side. Surprisingly, the answer is yes.

The cut is not machined by a traditional tool but instead is “modeled”. This uses a small diameter ball nose cutter and a small diameter square bottom tool. The ball nose tool moves along the profile, shifting over a small distance each pass until the basic shape of the profile has been generated. Then, sharp inside corners are finished using the square bottom tool. This same approach works on a symmetrical cut when the required profile cutter is not available. It can be especially valuable on wide or complex moldings where tooling cost might otherwise be substantial.

Profile tools are created by first creating a closed geometric shape and then using this shape to create the tool. Geometric shapes created in this area can be saved and then loaded and used again.

The *Shape Manager* operates in a separate window and consists of a basic two-dimensional CAD system. The background grid appearance, axes display and pick box size are controlled through *Grid Settings* reached through the *Grid Settings* icon or through the *Grid Settings* selection from the *Right Click Menu*.

While working in the *Shape Manager*, an area to the lower left offers step by step guidance for each function. There is also a place to enter X,Y positions manually.

The point where the X and Y axes cross is the *Origin* or the 0,0 point. The vertical Y Axis represents the centerline of the tool. The *Origin* or 0,0 point should be located at the bottom of the shape that defines the tool.

The *Zoom Controls* allow you to zoom in and out using either the + and – buttons on the display or using the + and – keys on the keyboard. In addition, you can hold the *Ctrl* key and pull a blue rectangle over the area you want to zoom to.

The *Entities* button zooms the scene to just include all the entities that currently exist.

The scene can be panned left and right and up and down using the arrow keys. If it doesn't seem to move, open the *Right Click Menu* and check that the *Pan Move Increment* is not set to zero.

A background grid and axes displays can help keep you oriented during the drawing process. These are controlled through a dialog accessed by pressing the *Grid* icon.

Also, because you are generally working in a smaller scene when creating tools, a *Local Settings/Preferences* dimension display is available through the *Local Settings/Preferences* icon. This allows you to select a numeric display for this area that is different than the rest of the program. Changing the numeric display here will not affect the display anywhere else except here.

Geometry is created using a series of tools, accessed by right clicking. Some of these tools (line, arc, circle, spline and mirror) create geometry. Others (fillet, chamfer, extend, trim, move and offset) modify geometry. Together, they can draw any two dimensional geometric shape. The same CAD engine used here is also used in other areas of the program. Once you learn how it functions, you will be able to use it in each of these areas.

Each of the tools that create geometry requires that points be precisely located. There are two ways to accurately locate points. First, you can type the X and Y coordinate position of the point by typing the X position, then a comma, then the Y position. Be sure to use a – sign for X positions to the left of zero or for Y positions below the zero point although normally the zero position on the Y Axis is the bottom of the tool.

The second way of precisely locating points is to set the grid spacing to an increment from which all required points can be reached and then turn on *Snap*. The cursor will then position on the grid points and it is simply necessary to move it to the desired point. It is normally necessary to zoom in enough that the individual grid points are far enough apart that they can be accessed easily.

*Object Snap* is another useful tool. With *Object Snap* turned on, the cursor will snap to the end point of a line or arc if it is within the *Pick Box* when the mouse is clicked. This assures that there is a continuous unbroken path between geometric entities which is important when you begin to use the geometry to create a tool.

The tools used to create geometry are straightforward and the *Guide Info* area displays each step as you do it.

Create lines by specifying each end point.

Create a three point arc by specifying the start point, one intermediate point and the end point.

Create a circle by specifying the center and the radius.

You can also create a *Spline* curve, which is a smooth curve through several points. Enter the *Spline* mode and begin specifying points on the curve. Press *Esc* to exit the *Spline* mode.

Once created, these entities can be mirrored or modified.

To create a mirror image of geometry, start by highlighting the geometry you want to mirror. Then press the *Mirror* icon and indicate what you want to mirror the geometry about. You can mirror about the X Axis, the Y Axis or a line.

A *Chamfer* or a *Fillet* can be placed at the intersection of two lines or arcs. To modify a *Chamfer* or *Fillet* you must first erase the existing *Chamfer* or *Fillet* using the *Delete* mode and then define the new one.

Lines, arcs and circles can be trimmed at their intersection.

To trim a single line at an intersection, select *Trim-Trim One*, click on the line portion you want to keep, then click on the entity that it intersects with.

If the original line extended past the intersection, it will be trimmed to the intersection point and the section of the line you didn't click on is discarded.

If the original line did not extend to the intersection, it is extended until it intersects.

To trim two lines at their intersection, select *Trim-Trim Two*, click on the portion of the first line you want to keep, then click on the portion of the second line you want to keep. If the two lines intersected, they are trimmed at the intersection point, keeping the portion of each you clicked on.

If either line did not extend to the intersection, it is extended until it intersects.

Note, in either case, arcs extend along the arc path to the intersection.

When trying to create a tool from your geometry, at times, you may be notified that the path you selected is not a closed path. The *Trim Two* function can be very useful in correcting this. Simply trim each intersection until the open intersection has been closed.

A *Circle* can also be trimmed. To understand how this works, think of a circle as a 360 degree arc with both the start and end points located at 3 o'clock to the right.

The circle is then made up of two sections, one that starts at 3 o'clock and extends counterclockwise to the first intersection and a second section that starts at the intersection point and extends counterclockwise back to the 3 o'clock or zero position.

When trimming, the section of the circle you first click on will remain and the other section is discarded.

In the above example, if you click on the section labeled *First Section* and then select the line, the entire arc labeled *Second Section* is trimmed leaving only the first section.

If you click on the arc labeled *Second Section* and then click on the line, the arc labeled *First Section* is trimmed away leaving the arc labeled *Second Section*.

Sometimes when trimming a circle, you may need to perform the trim operation more than once. For example, if you wanted to keep the arc located above the line, you first need to trim away the first section. Now it is no longer a circle but is an arc and will trim like an arc segment. Perform a second trim to remove the arc between the zero point and the line by clicking on the arc above the line and the trimming to the line.

To keep the arc below the line, click on the second section below the line and trim to the line. In this case, everything from the intersection to the lower left to the zero point will be gone. Then, trim the lower arc back to the line and it is extended until it meets the trim line.

Experimenting with trimming circles combined with the above explanation will make this clear.

Lines and arcs can be extended by a fixed distance by selecting the *Extend* icon. A dialog will ask for a distance to extend. After entering a distance, whichever end of a line or arc you click on is extended. Note that arcs extend along the curved arc path.

The *Offset* command, when applied to an entity, either creates an offset copy of the entity or offsets the entity a fixed distance. This command is executed by selecting the *Offset* icon or selecting *Modify – Offset* from the *Right Click Menu*. In the dialog that appears, you set the offset distance and select whether the entity is copied or moved.

Then, click on the entity you want to offset and then click the side of the entity you want to offset to.

Offset straight lines are the same length as the original. Offset arcs have the same included angle as the original as seen to the right.

The *Move* command is used to move an existing entity. The entity must be selected BEFORE the *Move* command is initiated. Press *Esc* to cancel any current modes and enter the select mode and click on the entity you want to move. Then press the *Move* icon or select *Modify-Move* from the *Right Click Menu*. You will now define two points. The entity will move a distance the same as the relative distance between the two points.

Entities can be deleted by entering the *Delete* mode. Press the *Delete* icon or select *Delete* from the *Right Click Menu* and several *Delete* modes are available.

*Single Delete* will delete any single entity that you click on. When in this mode, any single entity you click on is deleted.

*Inside Window* will open a mode where you can pull a red rectangle or window using the mouse. Any entity that is completely within the window is deleted. An entity that touches or crosses the window frame is not deleted, the entity must be completely inside the window.

*Inside Intersect Window* also opens a mode where you can pull a window, however, in this mode any entity that has any part of it inside or touching the window is deleted. Finally, *All Entities* does just what it says, it deletes everything.

*Undo* can be a lifesaver. It reverses or undoes that last thing you did. It only goes back one step, however, pressing it reverts to the state you were in prior to the last action you took.

Once the geometry is complete, you can create a tool using the *Create Tool* icon or by selecting *Create Tool* from the *Right Click Menu*. To create a tool, you must have closed geometry. This means that the outline must be a continuous closed curve with no gaps or openings.

Tool shapes should generally be drawn symmetrical with their full shape. It is possible to draw a tool whose left and right sides have different profiles and, when applied to a part, it will cut a different profile on each side of the cut. You cannot use a rotating router bit to actually cut this shape, however, as discussed earlier this asymmetrical shape can be modeled using standard modeling tools.

The tool diameter is the shank diameter from the beginning of the cut profile on one side to the cut profile on the other side. This is also generally the diameter of the shank that mounts in the router collet. This diameter will be needed when the tool is applied to an edge in the *Part Editor*.

To create a tool file you simply need to press the *Create Tool* icon, then select the closed curve by clicking on it to highlight it. Press the *Next* button then specify a file name to save the tool under.

We will now develop a simple tool as an example. The image to the right shows the edge part profile we would like to create a tool for.

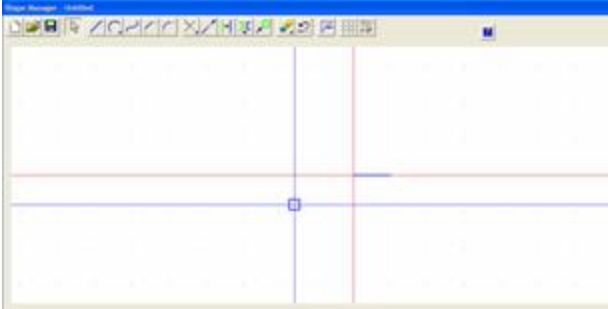

Open the *Shape Manager* and select *Line Mode*. We will use numeric input for this design.

We will make the tool  $\frac{1}{2}$ " shank diameter.

Start at 0, 0.

The second point is .25, 0. .25 is in the plus direction on the X axis, which is to the right. We now have our first line which defines the bottom of the bit.

It is now a good idea to zoom to the area we will be working in.

Hold the *Ctrl* key and pull a blue rectangle over the working area.

Here is what we have so far, after zooming.

Notice that we are still in the *Line* mode. When a mode is selected, you remain in that mode until you either change it or press *Esc*, which puts you in a default or *Select* mode. This allows you to select individual entities, primarily so that you can *Move* them.

We will now create the circle segment on the right side of this line. Make sure *Object Snap* is turned on by right clicking the mouse and verifying that it is checked.

The circle will have a  $\frac{1}{2}$ " radius so enter the *Circle – Circle* mode. Input .75,0 for the center of the circle. Then, place the pick box over the right end of the line and click. A circle is created.

We need to trim the circle, but first we will add the rest of the straight line which we can then use in this trimming process.

Enter the *Line Mode*.

Draw the first line from .75, 0 to .75, .75.

Finally, click on the top of the line we just drew and input the end of the line at 0, .75 creating a line across the top to the Y axis.

This is the result so far.

We are now ready to trim the circle. This area can get a little tricky so we will detail it step by step.

Select the *Trim Mode – Trim Two*.

Select the upper left quadrant of the circle marked (1) as the first entity to trim. Then select the upper portion of the line marked (2) as the second entity to trim.

rotating router bit. It can however, be used in eCabinet Systems to create a machined channel in a part that has a different profile on each side as shown.

Depending on the actual shape, the resulting part may not be able to be machined using traditional techniques.

When sent to a Thermwood CNC router, however, these shapes can be modeled.

Modeling consists of machining with a 1/8 or 1/4 inch ball nose router bit that steps over .01" to .02" each pass as it develops the shape. Square inside corners are then machined using a square bottom bit.

The Thermwood control automatically develops the modeling program needed to make a part if a tool does not exist with the correct profile. Since a non-symmetrical tool doesn't really exist, any non-symmetrical machining must be modeled.

This ability to model almost any profile without specially ground tooling can dramatically decrease costs when a limited amount of production is needed. It also dramatically increases flexibility for shops that build custom products.

If the channel in the part is cut with a rotating router bit, inside corners are typically round with the same radius as the router bit. If you create a contour with square corners, the inside profile will be squared off as shown.

In this version of the software it is not possible to create a profiled corner on an inside cut that has a radius less than the radius of the router bit at its largest radius. For example, on our tool, the minimum fillet you can use is .75" which is the largest radius of the tool. At least for now, if you want to simulate the effect of the radius corner that results from using a router bit, you will need to use a fillet equal to the radius of the tool. This area will be addressed in future releases of the software.

## Benefits of Purchasing Through eCabinet Systems

Purchasing is the key driving force behind the software you are using. It is also an opportunity for you to save a great deal of time and perhaps some money. If you are interested in a CNC router in the future, purchasing through the program can also earn you a discount, perhaps a large discount on a Thermwood CNC router system.

Software similar to eCabinet Systems sells for thousands if not tens of thousands of dollars a copy and costs more EACH YEAR to maintain and update. Your copy of the software did not cost you anything. It was free, but software is not free.

It has taken years and well over a million of dollars to develop eCabinet Systems and it requires a huge investment every year to continue expanding and supporting the software. Portions of the software are licensed from others and in some cases, we must pay them for each copy. Although the software is free to you, it has a very real cost to the program. These bills are paid as the result of purchases that Members like you make through the eCabinet Systems program.

This is a win-win approach for both us and our Members if we both do our part. You buy a lot of items to run your business. Our prices are generally as good as, and in many cases better than what you are paying today. Therefore, purchasing through the program should not cost you anything.

In effect, you get thousands of dollars a year in software and service and if you work with us, it is all essentially free.

In addition, purchasing through the software also gives you an opportunity to earn discounts on Thermwood CNC router systems. By simply requesting it, we will track your purchases and place 5% of them in an account for you. These earned discounts remain in your account for five years or until they are used. At any time you can apply any or all of your account toward the purchase of a Thermwood CNC router system.

You can sign up for this program on the [www.ecabinetSystems.com](http://www.ecabinetSystems.com) web site under *CNC Router Discount Program*.

Your business requires that you purchase these items on an ongoing basis. It just makes sense to use these ongoing purchases to support the software you rely on and also generate a discount, perhaps a large discount on a modern CNC router system.

These are some compelling reasons to buy through the program but, you do have to change buying habits and for some this is difficult. Difficult as it might be, it is also very important. If you use the software you are changing the very core of how you run your business. These changes will benefit you substantially. While you are making changes, we ask that you also change your buying habits and begin using eCabinet Systems for all your purchases.

If you do, and sales through the program increase, more and more vendors will begin using the program to sell you their products. As they compete with each other, prices, the prices you pay will come down even farther. You will win again.

If however, you, and other Members use the software and use the service and call support and do not support the program and buy through the program, it will become impossible to continue investing in it and the program will eventually fail. At that point you can return to doing things manually on scraps of paper or you can shell out thousands or tens of thousands of dollars to actually buy software then pay every year to maintain it. Should this happen, we all lose.

eCabinet System Members have no legal obligation to purchase through the program. You do, however, have a moral obligation. If you use our tools and benefit from those tools, you should purchase through the program.

We have seen instances where current supplier have matched or even discounted below our prices to try to keep the business from going to eCabinet Systems. If you are getting these discounts, don't kid yourself, it is strictly because of eCabinet Systems. If you fall for this and decide not to buy through the program because of a few cents difference, the program will ultimately fail. You will lose thousands of dollars a year in benefits and soon, your old higher prices will be back, guaranteed.

This program is based on a truly cooperative approach and places a high level of trust in human nature. If we all work together, we all benefit. If instead, everyone enjoys the program benefits but relies on others to support the program through purchases, it won't work long term.

The software offers another major advantage to traditional purchasing. It tracks everything you need to purchase while developing the Job and allows you to purchase these with the push of a button. This saves time and your time is worth money. When analyzing costs, be sure to take into account the time savings in addition to actual component cost.

## Using the Shopping Cart

### *Using the Shopping Cart*

The buying process in eCabinet Systems is actually quite straightforward and easy. We will go through the process in detail but you do not need to deal with most of the details unless you want to.

Buying is a two phase process. First, the *Shopping Cart* is used to gather items you want to purchase. Then you go through a checkout process.

A *Shopping Cart* is associated with each Job. If you have two Jobs, there is a separate *Shopping Cart* for each Job.

There are two ways to put items into the *Shopping Cart*. First, purchased items from *Batch Input* and *Custom Layout* are automatically placed in the *Shopping Cart*. These are items associated with cabinets in those areas. This also includes purchased items that were added to the *Custom Layout*. This happens automatically unless you indicate you don't want them.

The second way to add items to the *Shopping Cart* is to simply go shopping, select the items you want and add them manually.

During checkout you will fill out several forms indicating where to ship and how to pay. You only need to fill these out once. Once the information is input, it is stored and will be filled out automatically for you on subsequent orders. The only exception is your credit card information which, as a security measure, is not stored on your local computer where others may be able to hack it. In order for us to get paid, your credit card information must be retained on our highly secure server, therefore you can request that a card used previously be used again when you place a new order to save you the effort of inputting the data again.

### ***Manually Adding Items to the Shopping Cart - Overview***

From the *Shopping Cart* area, you can go shopping. You can explore all the categories of product offered and add any of them to the *Shopping Cart*. Let's take a closer look at this process.

AUTOMATICALLY INCLUDE BUY LIST

Three fundamentally different types of product can be added to the *Shopping Cart*. These are selected by three red buttons located at the upper right as shown.

The *Add Drawer Box* selection and the *Add Door/Drawer Fronts* selection both refer to purchasing these items from Conestoga. Each includes a dialog area that allows you to define the specific items you wish to add.

With respect to doors and drawer fronts, the items added here are in addition to doors and drawer fronts that are already on cabinets in the Job. When you add a door or drawer front to a cabinet, if you specify either *Purchase Finished* or *Purchase Unfinished*, the door in the correct size and specification is automatically added to the *Buy List* and subsequently to the *Shopping Cart*.

You will use this area when you want to specifically purchase doors or drawer fronts of a specific size and design in addition to any doors or drawer fronts already in the Job.

The *Add Drawer Box* area is used to order high-quality drawer boxes from Conestoga.

The third area, *Add Components* allows you to select from thousands and thousands of items that can be purchased through the software. These items include the typical cabinet hardware and components but extend to include almost anything a cabinet shop might need. Selections include tooling, sandpaper, tape and other disposables, virtually every type and size nut, bolt screw and nail, a wide variety of hand tools and almost anything else you can think of.

The cost of any items added to the *Shopping Cart* is automatically added to the *Cost Sheet* for that Job. If you want a purchased item added to the cost for a Job, load the Job and then add the item to the *Shopping Cart* for that Job.

You may want to purchase many of these items separate from a cabinet Job. In this case, start the software and go immediately to the *Shopping Cart*. There you can select and buy the items you want. As soon as you add an item to the *Shopping Cart*, a Job is created but the Job only has *Shopping Cart* items in it. The *Buy List* and *Cut List* are both empty but the *Cost Sheet* reflects the cost of the items in the *Shopping Cart*. At this point, you can save the contents of the *Shopping Cart* as an eCabinet Systems Job file (.esj).

This can be quite useful if you purchase the same items on a regular basis. Simply put the items in a *Shopping Cart* and save the Job. Then, any time you need the items, you can load the Job, go directly to the *Shopping Cart* and buy them.

## ***Adding Components to the Shopping Cart***

To reach an area where you can add a wide variety of items to the *Shopping Cart* press the button labeled *Add Components*.

This opens the huge vendor database. Now all you have to do is find what you want.

You have two choices. You can search the entire database for a part number or using words from the description or you can select the category of product you want from the list.

Most items needed by cabinet shops are found in the *Cabinet Supplies* area, however, power tools, tooling and other items are found throughout the offering.

You might want to explore the offering to become familiar with the types of products offered and the general layout of the vendor database.

The software may include vendors that you may not be familiar with. You can access a descriptive page that describes the vendor through the *Help* menu at the top of the page. Select *About Vendors* and then select the vendor you are interested in.

Once you select a category, you are presented with a list of item types for that category.

You now have a choice of how to proceed. You can select the item type, and then select vendor and browse to find the item you want.

You can also search the entire database for the part using the *Search* button. From this page, the entire database is searched, both the part number field as well as the short description field. If you know the manufacturer's part number, you can simply type it here and press *Search*. This will take you directly to the part. You could also search for the part by its description, "pull" for example.

From this screen, or the previous one, the *Search* button will search all

offerings for all vendors. Once a vendor is selected, the *Search* button only searches that vendor's product offering.

You can tell if there is an active vendor by looking at the center top for the vendor's logo. If a vendor logo is displayed, it means you are working within that vendor's database. Any *Search* command will only search that one vendor's database.

If, on the other hand, there is no vendor logo as seen on the first screen, the *Search* command will search every vendor database in the system for the part number.

It might help if you understand how eCabinet Systems handles part numbers. Part numbers for hardware and cabinet supplies in the software start with a two letter identifier followed by a dash and then the remainder of the number. These first two characters are the vendor identifier and are unique for each vendor. AM- for Amerock, HF- for Hafele, BL- for Blume, WT- for Wood Technologies, etc.

This two letter identifier is then followed by the part number the vendor uses to identify the component. When you search for a part you should use the vendor number without the two letter identifier just as the vendor supplies it.

The *Search* function returns a listing of every part that matches, either from the complete database, if the *Search* was conducted from one of the main screens or from the single vendor database if *Search* was run from a vendor screen.

The results are presented in pages of twelve.

At the bottom of each page you are shown the item numbers for this page, the total number of items and an area to click to bring up the next page of items.

The vendor database is presented to you in HTML format so the *Back* and *Forward* navigation icons work. These make navigation fast and easy.

The *Favorites* button offers a short cut to those items you purchase regularly. Pressing it opens a listing of all of the items you have added to the *Favorites*. There are a couple of ways to order from this list.

You can select items, one at a time, and add them to the *Shopping Cart*. A quantity dialog will appear for each part where you can specify the quantity of that part you want to order.

As an alternative, you can place a check mark in front of every item you want to add to the *Shopping Cart* and select *Add Checked Items to Cart*. In this case, you will be offered a single quantity dialog where you can specify the quantity. This same quantity of every item selected is added to the *Shopping Cart*.

If you need different quantities for different items, it is probably easier to add them all at once and then adjust purchase quantity in the *Shopping Cart* itself.

The decision as to whether to add items from *My Favorites* one item at a time or as a group using the check boxes is based on your preference. The final result is the same.

### ***Adding Items from Batch Input and Custom Layout to the Shopping Cart***

As you add cabinets and items to a Job, either using *Batch Input* or by adding them to a *Custom Layout*, the system tracks the items that must be purchased for the Job in the *Buy List*. You can print out or display a copy of this *Buy List* whenever you want. The list is dynamic and changes any time you change the Job.

A checkbox in the *Shopping Cart* determines if you want to add the items from the *Buy List* to the *Shopping Cart*. This checkbox, labeled *Automatically Include Buy List* can be checked or unchecked at any time.

If it is checked, all the items needed for your *Custom Layout* plus all the items needed for the cabinets added in *Batch Cabinets* are automatically added to the *Shopping Cart* along with any vendor items you may have added to the *Custom Layout*.

If you uncheck it, only items that you specifically add (we will cover that shortly) are in the *Shopping Cart* and none of the items required for either the *Custom Layout* or *Batch Cabinets* are included.

When you check *Automatically Include Buy List*, the *Shopping Cart* reflects the current Job. If you leave the *Shopping Cart* and make changes to the Job, when you return, all changes will be reflected in the *Shopping Cart*. The *Shopping Cart* always knows exactly what you need for the Job.

### ***Adding Doors and Drawer Fronts to the Shopping Cart***

This area is used to add doors and drawer fronts to the *Shopping Cart*. If you only want to purchase doors and drawer fronts for cabinets you have added to the Job in either *Custom Layout* or *Batch Cabinets*, you do not need to add any doors or drawer fronts here. Doors and drawer fronts for cabinets in the Job are automatically added to the *Shopping Cart* provided you check *Automatically Include Buy List* and you specified that the doors and drawer fronts are either *Purchased Finished* or *Purchased Unfinished* when you placed them on the cabinets.

Since currently the only outside source for purchased doors and drawer fronts is Conestoga, this area offers a simple way of purchasing Conestoga doors.

If however, you want to add additional doors and drawer fronts or simply want to place an order for these, this is the proper place.

When you press the *Add Door/Drawer Front* button, the *Door/Drawer Front Designer* opens. You can now select a door or drawer front design you previously designed and saved or you can develop and save new designs. You could also just develop a door design and add it to the *Shopping Cart* without saving it but we do not recommend this. If the design is worth developing and ordering, it is worth saving.

We are not going to detail operation of the *Door/Drawer Front Designer* which is covered in another section. Once the design is ready, however, we are ready to add it to the *Shopping Cart*. Press the *Add to Cart* button to bring up a dialog used to create a list of quantity and sizes of this item that you want to add to the *Shopping Cart*.

This dialog has been developed to work as a standard data input screen and makes it easy to enter lists of required sizes.

You step between fields using either the *Tab* or the *Enter* key. *Shift* plus *Tab* steps back one field.

To add a line, type the Length – *Enter* and then the list. This blanks all the first, *Quantity* field

With just a little lists of doors can be

Once all the sizes of list can be edited.

quantity, *Enter*, Width – *Enter*, press *Enter* again to add the line to the fields and moves you back to where the process starts again.

practice, data entry of even long both quick and easy.

this design have been added, the

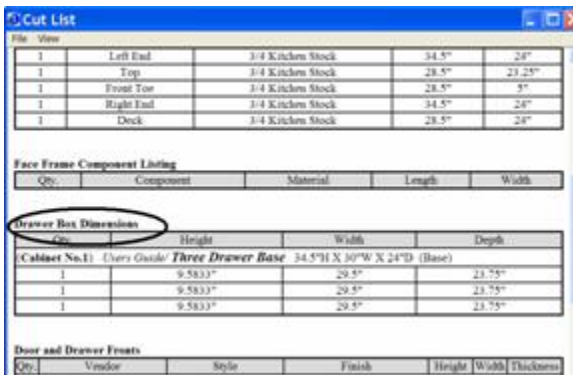

To delete a line, highlight it by clicking on it as shown. Now you can press the *Delete* button or use the *Delete* key on the keyboard.

To change any field in the list, first highlight the line and the double click on the field you want to change. It will highlight as shown and you can then make the necessary changes.

When the entire list is complete and correct, press the *OK* button to add it to the *Shopping Cart*.

### Adding Drawer Boxes to the Shopping Cart

This area allows you to define and add dovetail drawer boxes available from Conestoga to the *Shopping Cart*. You must determine the drawer sizes required and enter them here. This, however, is not difficult, as you will see.

If you run a *Cut List* for your Job, there is an area that provides you with the outside dimensions for the drawer boxes you will need. It is simply a matter of printing this

list out and entering it here.

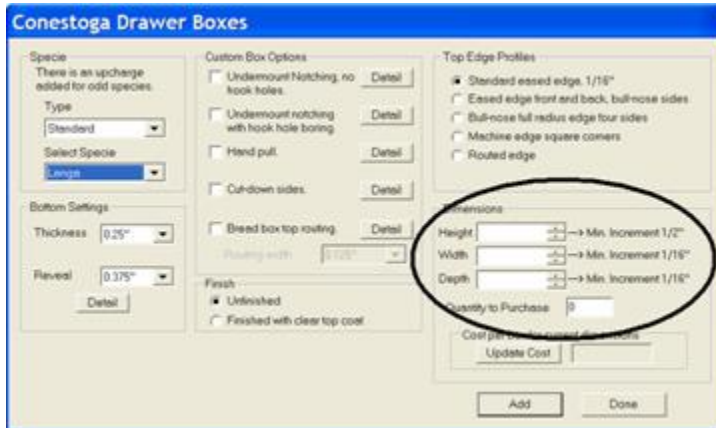

If you recall, when you set parameters in the *Door/Drawer* dialog in *Construction Settings*, you specified some information about the drawer boxes. This information is used to determine these sizes.

Shown here is the *Construction Settings* area where the drawer box size was determined. Drawer box size is set using a series of minimum dimensions. Since the drawer box is only available in certain incremental sizes, the software will assign the first available size for each dimension that meets the *minimum* requirements.

For example, the *Left* and *Right Insets* are available in 1/16 inch increments. You should set this increment to provide adequate clearance between the drawer box and the cabinet side for the drawer slide you selected. In this way you are assured of at least the

minimum clearance although the actual clearance could be up to 1/16 inch greater. Slightly more clearance is much easier to handle than slightly too little clearance.

So, from the settings you used when the cabinet was designed and the dimensions generated by the *Cut List*, you are ready to specify the drawers you want.

The *Height*, *Width* and *Depth* of each drawer box needs to be entered in the drawer box dialog as shown.

The only thing you need to watch is that the drawer boxes are not available in every size. They are available in certain increments so you must determine which way to round the number for your application. In general, you should round in the direction that makes the drawer box smaller, rather than larger, to assure proper clearances. In most cases, however, because of the rounding that goes on in the *Cut List*, you should be able to just use the sizes provided.

As we said earlier, we hope to better integrate this into the design process in future releases.

There are quite a few options and specifications that you can select for your drawer boxes. The software does a good job of describing and explaining these using the *Detail* buttons so we will not go over each here.

One really nice feature is the ability to determine the exact cost for any combination of features and options. Just press the *Update Cost* button to calculate a cost for the drawer box as currently specified.

When you are done just press the *Add* button and the drawer or drawers if you are buying more than one of this size, are added to the *Shopping Cart*.

## ***Understanding the Shopping Cart Layout***

The layout of the *Shopping Cart* has been carefully thought out and contains a huge amount of information. Understanding the layout and use of the *Shopping Cart* will make the entire purchasing process more comfortable.

Product	Qty.	Specifies where items in the shopping cart originated	Description	Type of Product	Unit Desc.	Unit Cost	Job Cost

modified while in the *Shopping Cart*. If you want to change characteristics of a door in the *Shopping Cart*, you can make the changes right here using the *Door/Drawer Designer* and then you can add the new design to the *Shopping Cart* as a new entry. Then, when you return, *Remove* the old entry.

Doors in the shopping cart because they are part of a cabinet cannot be opened.

The only way to change them is to actually change them on the cabinet itself.

The next column is the total number of the item in the *Shopping Cart*. This is how many you need, it is not necessarily how many you will buy.

When you move through the purchasing process, you will determine exactly how many you want to buy. Right now, this is simply a list of how many you need based on this Job and how many you manually added.

25.571" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	4	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	1.00	4.00
48 1/4" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	4	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	1.00	4.00
25.571" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	8	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	45.00	360.00

The next four columns tell you where the quantity actually came from. The column we just looked at told you the total number of each item you need. This area tells you what you need these for.

*Added Items* are those items you manually shopped for and

specifically added to the *Shopping Cart*. Other than you saying you wanted to buy them they have no other tie to the Job or to any other part of the software.

Because you added these manually, you can edit them right here. Press the *Remove* button to remove the entire item from the list. If you want to change quantity, click on the quantity and a dialog will open allowing you to change the number.

The last three columns show how many of each item are needed for other areas of the software. *Custom Layout Cabinets* means that this is the quantity of the item needed to build cabinets installed in the *Custom Layout* area.

Product	Qty	Specifies where items in the shopping cart originated			Description	Type of Product	Unit Desc.	Unit Cost	Job Cost
Job	1	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object				
2x2 Handle Nickel Plated Steel						Part	EA	4.12	4.12
875 V2 PE CUT CORNER HINGE	8	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Hinge	PER HINGE	13.98	96.72
800 X6 Translucent with clear vinyl individual	1	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Michael Dawson Organizers	EA	19.28	19.28
22x 26mm rubber line-free corner holdery shelf with adjuster	1	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Lady Searles	EA	10.00	10.00
25.571" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	4	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	1.00	4.00
48 1/4" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	4	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	1.00	4.00
25.571" X 14.6121" Hinge Side Right 1/4 Round Edge to Square C. Coverage Clear Hardware/Black Door	8	Added Item	Custom Layout Cabinets	Batch Cabinets	Single Object	Door	EA	45.00	360.00

These numbers are fixed and you cannot change them here. This is the number of items needed for the cabinets you installed and the only way to change it is to change the number of cabinets installed. Again, you don't necessarily need to buy all these, this is simply a listing of the requirements for this Job.

The amount you actually purchase is determined later.

The next column, *Batch Cabinets* does the same thing for cabinets placed in the Job through the *Batch Cabinets* area.

The final category is for *Display Objects*. In the *Custom Layout* area, you can select and position many items available from vendors. The thing that determines whether you can display an object or not is whether there is a three-dimensional image available for it. If there is, it can be placed in the *Custom Layout* as a *Display Object*. When this happens, the item shows up in the *Shopping Cart* in this column.

Again, you cannot change the number here, but remember, **this is not the quantity you will buy, it is the quantity you need**. Once you click *Order Now*, you can then specify the quantity you want to buy.

Before we order, we need to understand the *Unit Description* column.

This column describes exactly what you buy for the *Unit Price*. It lets you know if you are buying a piece (ea.), a box of 100, a set of three, etc.

Most items are available by the piece but there are exceptions, primarily for relatively low cost items such as screws, fittings, etc. In the case of these items, the software determines how many UNITS you need for the Job. For example, if you have a Job that needs 260 KD fasteners and they come in boxes of 200, it will indicate you need 2 Units (boxes). In these cases, you need to factor in the number of these items you have on hand and adjust the order quantity accordingly.

### ***Placing the Order***

Now, let's place the order. Click *Order Now*.

Here we see the same information reorganized into a *Buy Now* purchase order. Unlike the *Shopping Cart* which showed the quantity of each item you need for the Job, the *Buy Now* purchase order shows the number of items you will buy as the *Order Qty.* Let's look at this form in more detail.

The *Order Qty* column circled above is the QUANTITY YOU WANT TO BUY.

This quantity is initially set equal to the total number of items you need for the Job.

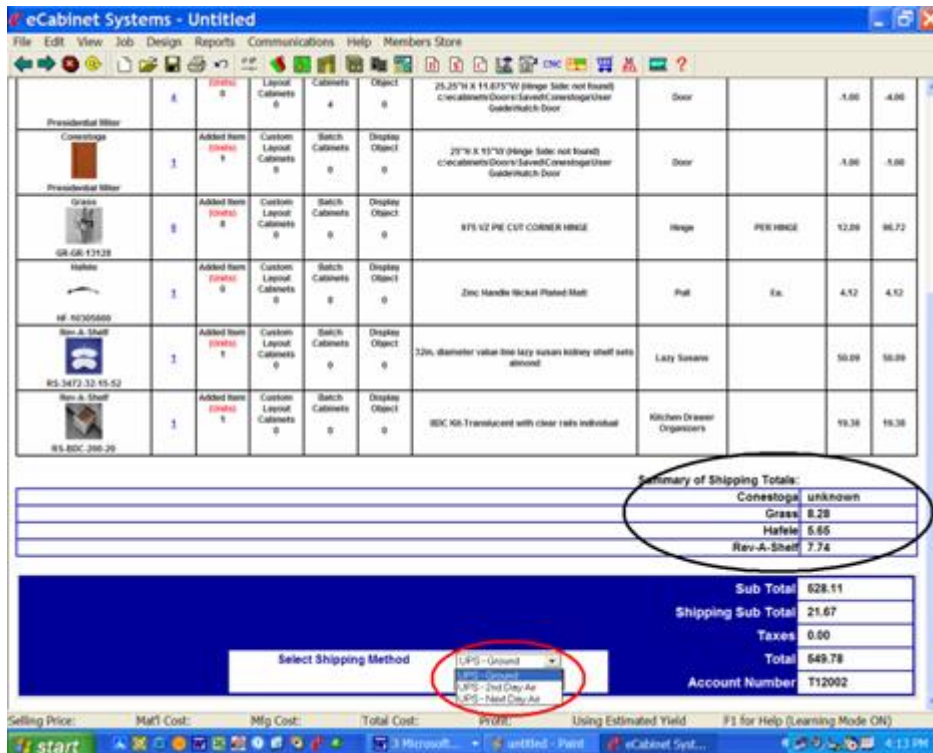

You can change the quantity to either more or less than what you need. If you not want to buy any of a certain item, set the quantity to zero.

To change quantity, click on the number you want to change and the *Enter Quantity* dialog appears. Change the number and press

*OK*.

Now, let's focus on the bottom part of the order form.

The black circled area is a summary of shipping costs for this order. Each vendor or source of product ships directly to you so there is normally a shipping cost associated with each. If no shipping cost is shown for a vendor it means that shipping is included in their price. This area details the exact shipping cost from each vendor. This is how much you will be charged for shipping.

The red circled area is used to specify shipping method. If you change shipping method, the system will calculate and display the new shipping costs.

Note that Conestoga shipping is stated as *Unknown*. In the case of doors and other large items, shipping is calculated on a per order basis depending on the overall order and shipping distance. In these cases you will be contacted directly with shipping cost and **YOU MUST AGREE TO THE COST BEFORE YOUR ORDER IS PROCESSED**. Until shipping cost has been communicated to you and you specifically agree, that portion of your order will not be processed. eCabinet Systems can provide a quotation for shipping prior to you placing the order should you want. Contact them directly for this type of quote.

The total purchases, total shipping, taxes and total order are then detailed at the bottom. Your account number is also shown.

If this is all correct and you wish to proceed, press the *Submit Order* button.

You will then see the *Security Alert* screen verifying that the coming transmissions will be fully encoded and secure.

Press *OK*.

## eCabinet Systems

The Cabinet Cooperative

### Billing & Shipping Information

Billing Information	
CompanyName:	<input type="text"/>
*Name On Credit Card:	<input type="text"/>
Contact Name:	<input type="text"/>
*Email Address:	<input type="text"/>
*Phone:	<input type="text"/>
Fax:	<input type="text"/>
*Address 1:	<input type="text"/>
Address 2:	<input type="text"/>
*City:	<input type="text"/>
*State:	<input type="text"/>
*Zip:	<input type="text"/>
County:	<input type="text"/>
*Country:	<input type="text"/>

You are now presented with *Billing and Shipping Information* form.

You will only need to fill this out one time and the information is then stored in your system and will be automatically entered when you access this page again.

Shipping Information	
Company Name:	<input type="text"/>
Contact Name:	<input type="text"/>
Email Address:	<input type="text"/>
Phone:	<input type="text"/>
Fax:	<input type="text"/>
Address 1:	<input type="text"/>
Address 2:	<input type="text"/>
City:	<input type="text"/>
State:	<input type="text"/>
Zip:	<input type="text"/>
County:	<input type="text"/>
Country:	<input type="text"/>

Note that the fields with a red asterisk must have an entry. The *Billing Information* is actually the address at which you receive your credit card bill. The name on the card and the *Billing Address* must match to avoid problems in billing.

You may notice that the *Shipping Address* information is all optional. If the shipping address is the same as the billing address you do not need to enter the information here. If, however, you want the product shipped to a different address than where you are billed you must complete the *Shipping Information*.

Note that we cannot ship to a PO Box.

Once your billing and shipping information is entered, it will be stored and automatically supplied the next time you access this form.

You may change the information any time you want, however, we attempt to monitor changes for security purposes, especially when the shipping address is significantly different than the billing address. If you make changes to your account information between Jobs we may need to call you to verify that you actually placed the order before actually processing it.

This is actually a reflection of what we received. We get your data, store it and then generate this receipt from our files. If it is correct, you are assured that we have the correct information in our files. The receipt also contains a telephone number to call if you have any questions at all.

The receipt is a full document much like the *Order Summary* we just looked at. It is stored as a file in the receipt file directory and can be accessed at any time using the *File – Receipt File* menu selection at the top of the page.

Remember we are a cooperative in every sense of the word. We want to make you money as we try to make money. If you have any problems at all, please let us know. If you made a mistake on the order or have any other problem, just give us a call and we will try to fix it. Standard commodity items like hardware are easy to fix. Products specifically built for you like doors can be a bit more difficult, depending on how far the vendors are into the building process. In either case, give us a call with any problem at all and we will do our absolute best to try and help.

By the way, THANKS FOR THE ORDER !!!

## Hot Keys

### *Hot Keys*

Throughout this guide we have been describing the functioning of the software based on the use of menus and mouse selections. There is another way of operating the software that, once learned, is substantially faster and easier, Hot Keys.

Most of us are familiar with hot keys. In most software a key or combination of keys can be used to perform functions that otherwise require menu selections using the mouse.

Hot keys do require learning. You must learn, and then remember the key or sequence of keys needed to launch a function. If, however, you plan to make extensive use of the software it makes sense to learn these key sequences because they will dramatically speed your input. For example, in a typical three level selection you must first set a mode by moving to and clicking on a mode button or icon. Then you must double click or right click to bring up a menu. Then you must move to and click on the menu selection. This opens additional selections. You must then move to and make the final selection.

Or, you can type three letters.

You do have to know and remember the three letters but just see how fast it is if you do.

You can get a list of all Hot Keys from the *Help* menu. We suggest that you print out the Hot Key list from the *Help* menu and keep it handy.

Let's look at the operation of the Hot Keys one area at a time.

### **Main Screen:**

F1 = Help

Ctrl + N = New Job

Ctrl + O = Open Job

Ctrl + S = Save Job

Ctrl + P = Print

Ctrl + E = Settings/Preferences dialog

Ctrl + Z = Undo last Action

Ctrl + X = Cut

Ctrl + C = Copy

Ctrl + V = Paste

The *Main Screen Hot Keys* consist of essentially commands that use the *Ctrl* key plus a letter. To function the *Ctrl* key needs to be held down when the letter key is pressed.

Most of these keys are the same as hot keys in Windows so many of you may already know them.

Some of these Hot Keys, *Ctrl + C*, *Ctrl + V* and *Ctrl + Z* are used in many areas of the software. Any time something needs to be copied or pasted, the standard *Ctrl + C* and *Ctrl + V* can be used. These should be used by pretty much everybody. There are a lot of places in the software where this is required and these are real time savers.

So is *Ctrl + Z*. This is the standard *Undo* command. It generally reverses the last thing you did. In Version 3.0, the *Ctrl + Z* or *Undo* command only works to restore an item that was inadvertently deleted in the *Drawing Editor* or in *Custom Layout*. It may be expanded in the future to other areas, but in its current form it can be a real lifesaver if you didn't realize certain items were highlighted until you accidentally delete them. If you remember *Ctrl + Z* it is quickly restored. Be sure to restore as soon as you realize you have a problem. As you continue to work, certain commands eliminate the possibility of restoring deleted items. Once you process one of those items, you are out of luck.

Also, if you change dimension display often, the *Ctrl + E* keys quickly open the *Settings/Preferences* area.

### ***Cabinet/Assembly Editor:***

F12 = Returns to the full screen view.

Home = Reset to the Front view.

### ***Wall Editor:***

Ctrl + A = Selects all walls when in overhead or all geometry when in elevation view.

Home = Zooms the screen to its full extents. (except when focus is on an entry box)

R = Reverses the Build direction of the wall currently being drawn or the highlighted wall(s).

S = Brings up the Right Click Menu in the Select Move Mode.

P = Brings up the Right Click Menu in the Place Item Mode.

F2 = Toggles between Select and Create mode.

F3 = Toggles Object Snap on or off.

F6 = Toggles Angle Snap on or off.

F7 = Toggles Screen Grid on or off.

F8 = Toggles Ortho mode on or off.

F9 = Toggles Cursor Snap on or off.

Arrow Keys = Pans the View area by the currently set move increment (except when focus is on an entry box)

Shift + Arrow Keys = Moves highlighted items by the currently set move increment.

+ Key = Zooms in on the view area.

- Key = Zooms out on the view area.

Delete Key = Deletes the last created wall or deletes currently highlighted walls or geometry items.

Esc = Aborts line, rectangle or circle creation as long as the second point has not been entered or deselects all highlighted items.

Shift + Home = When in elevation view will return back out to overhead view (must be in select mode).

Left Click + Drag Window = Creates a Select window. Any wall or geometry that exists inside the window will be highlighted once the left button is released.

Ctrl + Left Click + Drag Window = Creates a Zoom window. Zooms to the extents of the window once the left button is released.

Double Click on a Wall = In overhead will take the wall to elevation view (must be in select mode).

A = Adds highlighted geometry to a wall (elevation view only).

C = Cuts highlighted geometry from a wall (elevation view only).

N = Sets highlighted geometry to a neutral state (elevation view only).

There are a lot of things to remember here, but there are some great tools. Some of these should be learned and used by everyone while others are more for power users.

The *Esc* key is one of those that everyone should remember. Any time you are in the middle of anything and want to stop, the *Esc* key is a good bet. Most times it will do exactly what you want.

The final area for Hot Keys is *Detail Room*.

### ***Detail Room:***

Ctrl + A = Selects (highlights) all items in the room. (Excludes windows and doors placed on walls)

F2 = Toggles between Select and Place Item mode.

P = Opens the Right Click menu in Place Item mode. Allows further selection of hot keys listed in the menu.

S = Opens the Right Click menu in Select mode. Allows further selection of hot keys listed in the menu.

D = Moves highlighted display objects down by the currently set move increment.

U = Moves highlighted display objects up by the currently set move increment.

W = Switches display to wireframe.

Arrow Keys = Pans the View area by the currently set move increment.

Shift + Arrow Keys = Moves highlighted items by the currently set move increment.

+ Key = Zooms in on the view area.

- Key = Zooms out on the view area.

Delete Key = Deletes the last Cabinet placed or deletes currently highlighted items.

Esc = Cancels the active placement items or deselects all highlighted items.

Home = Zooms the screen to its full extents.

Shift + Home = When in elevation view will return back out to overhead view.

Left Click + Drag Window = In Select Mode, creates a Select window. Any wall or geometry that exists inside the window will be highlighted once the left button is released.

Left Click + Drag Window = In Place Item Mode, Creates a Zoom window. Zooms to the extents of the window once the left button is released.

Ctrl + Left Click + Drag Window = In any mode, Creates a Zoom window. Zooms to the extents of the window once the left button is released.

Double Click on a Wall = In overhead will take the wall to elevation view (must be in select mode).

It is in the *Detail Room* area where Hot Key sequences can save the most time. The listing of Hot Keys above include those that function from the *Main* operating area. Two of these keys, *P* and *S* open the *Right Click Menu* where additional hot keys are available.

*P* opens the *Right Click Menu* in the *Place Item Mode* and *S* opens the *Right Click Menu* in the *Select Move Mode*. Once the *Right Click Menu* is opened, additional Hot Keys access other menu selections. The Hot Key required to access the menu selection is shown to the right on the menu. By knowing the key to open the *Right Click Menu*, the menu can guide you through the remainder of Hot Keys.

From these, key sequences develop that directly access certain functions. Although you do not need to memorize these sequences, since you can look them up each time you open the *Right Click Menu*, it is quicker if you do. You can actually complete typing the sequence before the menu appears. Let's look at the sequences.

*PC* – switches to the *Place Item Mode* and brings up the dialog where we choose the item to place.

*PA* – when placing a cabinet in the *Place Item Mode* this brings up the dialog where the angle is controlled.

*PL* – locks and unlocks the angle of the cabinet being placed in the *Place Item Mode*.

*PIF* – sets the *Freestyle* mode for placement in the *Place Item Mode*.

*SIF* – sets the *Freestyle* mode for moving items in the *Select Move Mode*.

*PIB* – sets the *Align to Back* mode for placement in the *Place Item Mode*.

*SIB* – sets the *Align to Back* mode for moving items in the *Select Move Mode*.

*PIR* - sets the *Align to Front* mode for placement in the *Place Item Mode*.

*SIR* - sets the *Align to Front* mode for moving items in the *Select Move Mode*.

*PIC* - sets the *Align to Center* mode for placement in the *Place Item Mode*.

*SIC* - sets the *Align to Center* mode for moving items in the *Select Move Mode*.

*SSN* – removes selection from all items in the *Select Move Mode*. *Ecs* key does the same thing.

*SSA* – selects and highlights all items in the *Select Move Mode*.

*SSC* – selects and highlights all cabinets in the *Select Move Mode*.

*SSP* – selects and highlights all appliances in the *Select Move Mode*.

*SSB* – selects and highlights all base cabinets in the *Select Move Mode*.

*SSU* – selects and highlights all upper cabinets in the *Select Move Mode*.

*SD* – delete all highlighted items in the *Select Move Mode*. The *Delete* key does the same thing.

*SJAD* – this will change the doors on all highlighted cabinets to the current default door. You must be in the *Select Move Mode* to highlight the cabinets.

*SJAF* – this will change the drawer fronts on all highlighted cabinets to the current default drawer front. You must be in the *Select Move Mode* to highlight cabinets.

*SJAP* – this will change the door pulls on all highlighted cabinets to the current default door pull. You must be in the *Select Move Mode* to highlight cabinets.

*SJAU* – this will change the drawer pulls on all highlighted cabinets to the current default drawer pull. You must be in the *Select Move Mode* to highlight cabinets.

*SJF* – this will duplicate the highlighted cabinet in both directions to completely fill the wall. You must be in the *Select Move Mode* to highlight a cabinet.

*SJC* – this opens the *Cabinet End* dialog for the highlighted cabinet where you can define an applied end on the cabinet. You must be in the *Select Move Mode* to highlight a cabinet.

*SJR* – This will duplicate the highlighted cabinet to the right until the wall is filled. You must be in the *Select Move Mode* to highlight a cabinet.

*SJL* – This will duplicate the highlighted cabinet to the left until the wall is filled. You must be in the *Select Move Mode* to highlight a cabinet.

*SJE* – this will take the highlighted cabinet to the *Cabinet/Assembly Editor* where it can be modified. You must be in the *Select Move Mode* to highlight a cabinet.

*SJX* – expand the width of the highlighted cabinet until it just fits the space it is currently in. You must be in the *Select Move Mode* to highlight a cabinet.

*SJM* – this is reserved for the *Merge/Separate* command although the command is not available in this version.

*SJS* – this opens the *ReSize/Equalize* dialog where you can resize a single cabinet that is highlighted or equalize two or more cabinets that are highlighted. You must be in the *Select Move Mode* to highlight cabinets.

*ST* or *PT* – opens the *Standard Dimensions* area of *Settings Preferences* where you can modify standard dimensions that affect the placement of cabinets.

*SU* or *PU* – opens a dialog where you can change the size of utilities.

*SM* or *PM* – opens a dialog where you can change the *Edit Move Increment*, which is the distance items move in response to arrow key input.

*SOR* – opens the *Rotate Object* dialog where the highlighted item can be rotated. You must be in the *Select Move Mode* to highlight an object or cabinet.

*SOT* – activates *Texture Match* for a highlighted molding or *Display Object*. The molding or *Display Object* will take on the texture of the first item you click on after the command is activated. You must be in the *Select Move Mode* to highlight a molding or *Display Object*.

*SH* – toggled *Show Dimensions* on and off. When on, dimensions between two highlighted cabinets or between one highlighted cabinet and a wall are automatically displayed. You must be in the *Select Move Mode* to select cabinets.

*SP* or *PP* – recalculated cost and price information displayed across the bottom of the screen.

*SRC* or *PRC* – creates a *Cut List Report* for highlighted items or for the entire Job if nothing is highlighted.

*SRB* or *PRB* – creates a *Buy List Report* for the highlighted items or for the entire Job if nothing is highlighted.

*SRS* or *PRS* – creates a *Cost Sheet Report* for the highlighted items or for the entire Job if nothing is highlighted.

Although this appears to be an extensive list, the letters have a pattern that, once learned, makes it easier to remember. All sequences start with *S* or *P*, depending on whether the command can be accessed from the *Select Move Mode* or the *Place Item Mode*. Some commands can be accessed from both so the first letter can be either.

You may want to print out this list and also follow along on the menu selections as you learn to use the Hot Keys. After awhile, the sequences start to become second nature and you will find the speed at which you can work with the software increases dramatically.

***Drawing Editor:***

M = Displays all the Marker Nodes available for selection from this view.

## Software Reports to Help Build the Job

### ***Software Reports to Help Build the Job***

OK, the Job is done and sold. Now we have to build it.

The software offers some valuable tools to help you actually build the Job. The tools you use depend on how you are actually going to manufacture the parts.

### ***Cut List***

A *Cut List* is a report listing of all the parts you need to make for a cabinet or a Job. It lists the parts, material they are made from and their size.

An icon in the top toolbar launches the *Cut List* in a separate window. Certain areas of the software also have selections from right click menus that will run the *Cut List* report.

The first thing you must realize about the eCabinet Systems *Cut List* is that you can run a *Cut List* for any cabinet, combination of cabinets or an entire Job. A *Cut List* can be run from the *Cabinet/Assembly Editor*, from *Custom Layout* or from pretty much anywhere else in the software. Therefore, when you run a *Cut List* report, it is important to realize and understand where it is run from and exactly what it includes.

Also, the *Cut List* reflects the cabinet or job as it exists when the report is run. When the *Cut List* is run, the window that contains it remains open until you close it. Therefore, should you run a *Cut List*, then change the job, that *Cut List* report is no longer accurate although, until you close the window, you can still access it.

There may be times when this can be useful. You can run a *Cut List* for a job, then make a change and run it again. Both *Cut Lists* now exist in separate windows and you can compare them side by side.

From the *Cabinet/Assembly Editor*, the *Cut List* reflects any cabinet or combination of cabinets that are highlighted. If nothing is highlighted, the *Cut List* reflects everything currently loaded in the workspace.

It works pretty much the same way in *Custom Layout*. If one or more cabinets or items are highlighted, the *Cut List* reflects those items. If nothing is highlighted, the *Cut List* reflects the entire Job.

It is important to note that in this case, the *Cut List* not only includes everything in the *Custom Layout* but also includes any cabinets loaded in the Job through *Batch Input*.

## **Buy List**

A *Buy List* is a report listing of all the parts you need to buy for a cabinet or a Job.

An icon in the top toolbar launches the *Buy List* in a separate window. Certain areas of the software also have selections from right click menus that will run the *Buy List* report.

As with the *Cut List*, you can run a *Buy List* for any cabinet, combination of cabinets or an entire Job. A *Buy List* can be run from the *Cabinet/Assembly Editor*, from *Custom Layout* or from pretty much anywhere else in the software. Therefore, should you run a *Buy List*, then change the job, that *Buy List* report is no longer accurate although, until you close the window, you can still access it.

Also, the *Buy List* reflects the cabinet or job as it exists when the report is run. When the *Buy List* is run, the window that contains it remains open until you close it. Therefore, you can run a *Buy List*, then change the job and that existing *Buy List* is no longer accurate although you can still access it.

There may be times when this can be useful. You can run a *Buy List* for a job, then make a change and run it again. Both *Buy Lists* now exist in separate windows and you can compare them side by side.

From the *Cabinet/Assembly Editor*, the *Buy List* reflects any cabinet or combination of cabinets that are highlighted. If nothing is highlighted, the *Buy List* reflects everything currently loaded in the workspace.

It works pretty much the same way in *Custom Layout*. If one or more cabinets or items are highlighted, the *Buy List* reflects those items. If nothing is highlighted, the *Buy List* reflects the entire Job.

It is important to note that in this case, the *Buy List* not only includes everything in the *Custom Layout* but also includes any cabinets loaded in the Job through *Batch Input*.

All the items in the *Buy List* for the current job are automatically added to the *Shopping Cart* which you can then use to actually buy these items. It is important to note that whenever the job changes, the *Buy List* items in the *Shopping Cart* automatically change to reflect the change. You do not need to run the report or do anything else. The *Buy List* as reflected in the *Shopping Cart* is always accurate and up to date.

## **Nest Diagrams**

If we are going to cut the parts out using any technique other than nested based CNC machining we will need to lay them out on full sheets of material. This is a process that has become known as “nesting”. When this process is complete, we will also know

exactly how many sheets of material will be needed for the Job. This nesting process can be done by the software.

If we are going to process the parts on a CNC router, we really don't need to nest the parts here in the software, since the final nesting process will be done at the machine. There is a reason, however, to nest the parts in the software even if you are going to use a CNC.

Once a Job has been processed through nesting, the software knows exactly how much material is needed. Then, and only then, will the *Cost Sheet* be really accurate. Until the nest is run, the *Cost Sheet* uses estimated yield to calculate cost. Once the nest is run, it uses the actual cost, because it knows exactly how many sheets it will take to make the parts.

The nesting area is also where you can get printed diagrams of the layout of parts on each sheet and shop drawings of each part.

Before we actually perform a nest, let's take a look at the available controls.

The nesting area is accessed through an icon in the top toolbar.

At the very top is a selection for *Nest Type*. Two selections are available, *Cut Line* and *True Shape*.

These define two different methods of developing the nest. The one you select depends on how you will process the parts.

A common way to cut parts from sheets is to cut them into panels using a panel saw or table saw and then perform any additional machining on the rectangular panels.

To be able to do this, however, requires that the parts be lined up along cut lines. We need to be able to cut all the way through the sheet separating panels without cutting into adjoining parts.

This is called a “Cut Line” nest. Parts are lined up along cut lines.

If parts are to be machined on a CNC router there is no real need to line them up. In fact, for odd shaped parts we could actually interweave them.

This approach is called “True Shape” nesting and, depending on the Job, can save material and result in better yield.

Cut Line Nest - parts lined up along Cut Lines

True Shape Nest - parts are nested without regard to Cut Lines

The next selection is the *Nest Direction*.

This determines whether the software nests the Job across the bottom first and then vertically or up the side first and then across.

In *True Shape* nests, this can affect the yield, so both directions should be tried and the one with the best yield used.

For *Cut Line* nests, this determines whether the first saw cuts are rip or cross cut.

We will skip the *Print* area for now and jump down to *Collar*.

Sheet stock seldom has edges that are smooth, square and finished adequately enough for cabinet applications. Therefore, it is usually necessary to trim the outside edges when we are machining the sheet.

In order to do this, we must allow some material around the entire edge of the sheet. This trim material around the edge of the sheet we call the *Collar*.

Above are nest diagrams for three sheets of material using a 2" collar.

Normally an eighth to a quarter of an inch is sufficient for most applications but we used a large collar here to make it easier to see the effect.

The *Collar* dimension is reserved around the entire sheet and parts are not nested into this area.

The next area to consider is the width of the saw blade or router bit.

Both of these parameters are defined in the *Standard Dimensions* area of *Settings/Preferences*. There are two input fields, *Saw Blade Kerf* and *True Shape Nesting Cutter Diameter*.

If you select *Cut Line* nest, the *Saw Blade Kerf* width is used between parts.

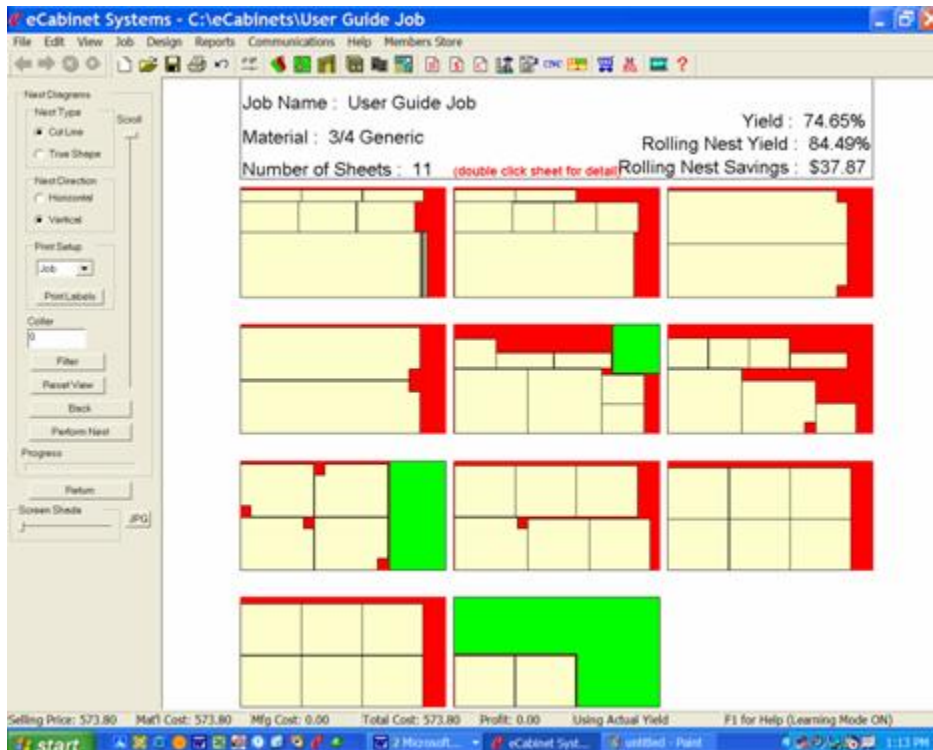

If you select *True Shape* nest, the *True Shape Nesting Cutter Diameter* is used, although this is not necessarily the gap between parts.

The actual space in *True Shape* nesting is slightly larger than the tool diameter. The software creates the program to cut each side of each part independently.

This is because you cannot ever get exactly the diameter tool you want.

To get accurate sized parts, the program must be adjusted for the exact diameter of the tool by a feature called *Tool Radius Compensation*. For this to work, each edge of each part must be cut separately.

The only thing you need to know is where the separation between parts comes from (*Settings/Preferences – Standard Dimensions*) and that for *True Shape Nesting* the result will be the same using a tool that is approximately the diameter you specify.

Above is a typical output for a *Cut Line* nest. Let's look at the various features of this output.

At the top is the Job name and the material. If the Job uses more than one material, nests for each material are grouped together. The vertical *Scroll* bar is used to scroll down the list of sheets.

The total number of full sheets is shown, in this case 11.

The yield for this Job is shown assuming that all 11 sheets are used and that you discard any material left over. There are also two lines concerning *Rolling Nest Yield*. This is a good time to examine nests, yield and a concept called *Rolling Nest*.

If you look at the nest diagrams, you will see different colors.

These colors actually have meaning.

Tan parts are the actual parts needed for the Job.

Red areas are scrap.

Green areas are also scrap for purposes of the standard yield calculation, however, they are large enough to be used on new jobs if some way could be found to use them. This is where the concept of *Rolling Nest* comes in.

If the system knew the sizes of material or drops left from the last job, it could start by nesting parts on those pieces and then continue the job using full sheets. Although this is a simple idea, its execution in the real world is a bit tricky.

The most obvious approach is to simply keep track of the drops in the computer and then use them the next time you run a nest. As simple and straightforward as this sounds, it presents some serious problems in a real shop.

When you use the drops in the new nest, you need to somehow communicate back to the machine which drops to use, in what order and how to orient them for machining. This is not all that easy.

Sometimes, it can be awhile between jobs that use the same material. What if the operator can't find the drops he needs after the programs are written for them? What if they were used for something else? In the real, practical world, the simple straightforward approach does not work. It commonly costs more trying to use this material than you possibly save in improved yield.

Many of these problems disappear if you can create the nest and CNC code at the CNC machine, rather than in the office. At the machine, just before you are ready to run the job, you know exactly what material you have handy. It is right there in front of you.

If there was an easy way to identify the drops and tell the control the order in which you want to run them, it would actually be practical to use them.

This is the basic idea behind *Rolling Nest*.

In addition to creating nests at the control, the *Rolling Nest* package also includes two printers. One prints a diagram of each nested sheet, identifying parts on that sheet. The second prints an adhesive backed label for each part.

The operator uses the diagram to identify the parts and places a label on each.

In addition to normal text information, some of the part labels also have a bar code. Actually two different types of parts have a bar code on their labels. The first includes all parts that need to be machined from both sides.

Some parts have machining operation on both sides. They need to be turned over and located and then the back side machined.

There are two requirements for this. First you must properly orient the part for the flip operations and then you must load the correct CNC program. The part label accomplishes both.

When the label is placed on the part after the front side machining is complete, it is always placed in a specific location. The location of the label is then used to properly orient the part when it is flipped over.

The part label also has a bar code. This bar code tells the control what CNC program to load. Just scan the label, locate the part and press *Start*.

The second type of part that has a bar code on its label is a drop.

Whenever a piece of scrap is larger than a minimum size, a bar code label is printed for it. This bar code identifies the size, shape and material.

As you might imagine, you can set the minimum size drop you want to save. For *Rolling Nest* yield calculations in the eCabinet Systems software we set this size as 18" x 18" but different shops use different sizes. There are also some other sophisticated touches to managing drops.

The actual shape of the scrap can be unhandy, with protrusions, lips and narrow outcroppings. During machining the system squares off the drop, cutting away any areas that are not suitable for nesting. The result is a rectangular or possibly an L shaped drop that is both easy to handle and practical.

Using drops in a new Job is easy.

When the Job starts, the system asks for any drops you might want to use.

Scan the drops in the order you want to run them and generate the nest. Parts will be nested on the drops first, in the order in which you scanned them. The remainder of the Job is then nested on full sheets and labels are printed for any remaining drops.

This approach makes using material from one Job on another truly practical. It requires little effort and the resulting improvement in yield can be significant.

While we are discussing *Rolling Nest*, there is one other aspect that makes it an incredible tool. This is called *Easy Link*.

*Rolling Nest* of course accepts Jobs from eCabinet Systems. Each Job is actually a collection of all the parts needed for the Job. You can, while setting up a *Rolling Nest* job, combine two or more eCabinet Systems Jobs. *Rolling Nest* will intermix the parts, trying to achieve the best yield.

In addition to parts from eCabinet Systems, *Rolling Nest* also accepts parts from every other major cabinet design software and every major CAD system. Not only does it accept these parts but it can accept parts from multiple sources in a single job and will intermix these parts to achieve the best nest.

As incredible as this is, it gets even better.

To understand this next part we need to talk a little about how CNC programs are created.

First comes the design.

Parts can be designed on a variety of software systems. These are collectively referred to as CAD or Computer Aided Design. The CAD system develops a geometric representation of the part. This design can be saved in a number of formats. Most CAD systems have their own format but, virtually all can also save the design in a format called DXF.

The DXF format came from a software company called AutoDesk, developers of AutoCAD. These were the first folks to develop a CAD system for PCs and they stored their files in a format they called data exchange format or DXF.

AutoCAD was quite successful which inspired others to create their own CAD systems. Since there were so many AutoCAD users, each new system needed to read and write to the DXF format so it became a type of unofficial standard. You will see why this is important in a minute.

Now back to how we generate CNC code.

Once we have a design, we must prepare it for CNC machining.

There are a lot of additional things needed before we can machine the part we designed.

First, the geometry is probably not in the correct order. The various geometric entities that make up our part are likely in random order, a result of our design process. It won't work very well to try and machine the parts in this order.

To get an idea of this problem, watch a pen plotter sometime. It draws the parts in the order in which they appear in the design file. It skips all over the place, apparently at random until the drawing eventually emerges. This works for plotters. It will not work for CNC machines.

So the first thing we need to do is to re-order the geometry. We need to determine the direction we want to cut and then string the entities together, reversing some, to generate a continuous part outline from start to finish.

We are, however, not done yet.

The geometry we now have is the part itself. What we really need is the path the tool must take to make that part. Therefore, we must offset the tool path from the part and generate the tool path required.

Still not done.

The machine itself will have certain requirements to get a good part. Some parts may need a lead-in and/or lead-out. This means you start off the part, begin moving and then move onto the part, machine it and end off the part again. This can get quite sophisticated.

When using Universal Vacuum to hold the part, it may be necessary to cut the part in two passes, the first leaving a thin skin and the second cutting the skin away. In this way, smaller parts can be cut without moving. So, the system must decide if any of these special features are needed and add them to the program. You might want to start and end along the longest end of the part which also minimizes the risk of moving. In a nest, you may want to machine the smaller parts first and then the big parts so the big parts can hold the small parts in place for as long as possible. While we are at it let's make sure the joint between the small part and the big part is the last one to get cut away.

This has all gotten pretty complex, but we still aren't done.

What we now have is a tool path. We know the path the tool must take to cut the part.

We now have to go through another piece of software to tailor the program to each machine we want to run on. You see, the same program cannot run on any CNC machine.

In fact, a typical CNC program can only run on one CNC machine. You have to create a different program for every machine, even to make the same parts.

#### WHY?

It is because no two CNC machines are the same. A good example is a machine with a router spindle and a separate drill head. Let's say the drill is mounted to the left of the router.

In order to switch from routing to drilling the machine must shift to the left. No problem, just program the machine to move to the left.

What if you try to run this program on a second machine, but the drill is on the right on this machine, not on the left. The program will shift to the left which clearly won't work.

You need a different program to make the part on this machine.

You would encounter the same problem if the drill was on the left on this machine but was not in exactly the same location as on the first machine. Unless the machines are absolutely identical, you will need a slightly different CNC program for each machine.

It is impossible to make the machines absolutely identical.

The industry handles this by using a software program called a *Post Processor*.

A *Post Processor* is created for each machine. This program knows all the mechanical details about the machine and adjusts the program to run properly on that one machine.

So, that's how the industry created CNC programs before *Rolling Nest*. Part designs created on a CAD system were processed through CAM software that reordered the geometry, offset for tooling, adjusted for special requirements of the machine and output center line data. This data was then run through a *Post Processor* for the particular machine it would run on.

*Rolling Nest* has changed all that.

As we said earlier, all major CAD systems and kitchen design software outputs their designs in DXF format.

*Rolling Nest* can accept these DXF files directly from the CAD system without the need for CAM, *Post Processor* or any further processing. All the work we just described is done inside the CNC control.

It is all automatic.

Not only can it create CNC programs for these parts but it can nest them with DXF parts from other CAD systems in the same nest. Imagine, you can have parts from multiple design sources nested together in the same job.

So as you can see, *Rolling Nest* is a powerful package, but what if you don't have access to a Thermwood CNC router?

There is an additional tool in the eCabinet Systems *Nesting* package that might help. It is called *Filter*.

*Filter* is used to filter out or remove certain parts from the nesting process. As it naturally exists, every part of every cabinet in the Job is nested. When you press the *Filter* button, a dialog opens where you can identify certain parts that you want removed from the nesting process.

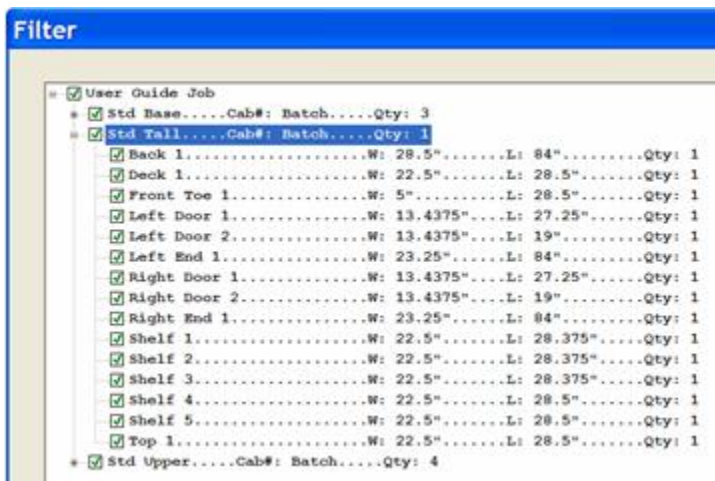

When you first open the *Filter* dialog, the Job name is displayed.

Click on the plus sign to expand the Job to show a list of cabinets that make up the Job.

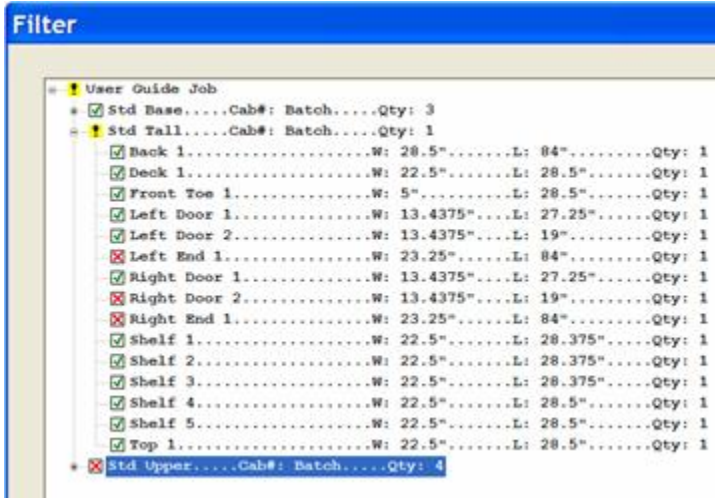

Notice the green checkmark in front of each of the cabinets. This means that the cabinet is

included in the nest.

Click on the plus sign in front of one of the cabinets to get a list of the parts that make up that cabinet. Again notice the green checkmark in front of each of the parts.

Again, this means that all these parts are included in the nest.

Here we have clicked on several checkboxes, changing them to a red X. The red X means that these parts will not be included in the nest.

Notice that we also clicked on a cabinet with qty 4. The red X means that this line item, all four cabinets and all parts for those cabinets will not be included in the nest.

Also notice the yellow exclamation point symbol in front of Std Tall cabinet and in front of the Job name. This means that somewhere in the Job parts have been filtered and somewhere in the Std Tall cabinet parts have been filtered.

When you can see all the parts it is not important but if you collapse the presentation as shown, it indicates that somewhere in the list, parts are filtered out.

filtered out.

Let's look at some places where this can be useful.

Let's assume you have a standard job you run repeatedly, a dormitory layout perhaps. Perhaps on the new run you have a couple of cabinets left over.

Instead of changing the saved Job, you can simply filter out the cabinets, producing everything but those cabinets.

Another possible use would be to offer a method of using some larger pieces of scrap, or drops, when cutting parts manually. Instead of throwing this material away, you could find a few parts and manually nest them on the drop. Then filter them out of the Job, nest

and run the rest of the parts. It takes a little more work but does save material. Now let's go back and look at some additional output from the Nesting system.

When first run, the nest displays all the nests for the entire Job,

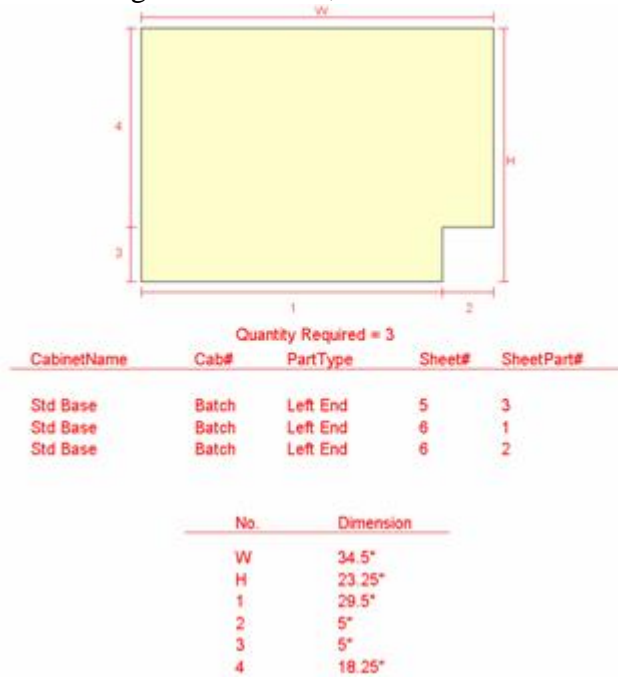

Sheet 5 (double click part for detail)

No.	Cabinet	Cab #	Part	Width	Height
1	Std Upper	Batch	Back	28.75"	28.5"
2	Std Upper	Batch	Back	28.75"	28.5"
3	Std Base	Batch	Left End	34.5"	23.25"
4	Std Upper	Batch	Right Hinge Door	26.875"	12.875"
5	Std Upper	Batch	Left End	28.75"	11.25"
6	Std Upper	Batch	Right End	28.75"	11.25"

color coded and three across. This gives you a general idea of the scope of the job as well as summary of material requirements.

For a more detailed look at a single sheet, double click on it. You will then see a more detailed view of the sheet including dimensions as shown.

The text is shown in red because this display reacts to the *Screen Shade* slide control and if the background is black, black text would not show.

You can now double click on any part on this screen to bring up a part display as shown.

This display provides all the data needed to make the part.

To move back to the last screen press the *Back* button to the left. Note that the *Back* icon on the toolbar does not work in this area since this display is not HTML. The *Back* button, however, does the same thing.

At any time you can press the *Reset View* button and return to the top display page.

Now that the nest is complete, you can print drawings for the Job as well as labels for each part. Let's start with drawings.

There are three selections for what you might want to print, *View*, *Sheets* or *Job*.

You select *View* you print a single sheet showing the view you currently see on the screen regardless of what it is.

*Sheets* print a page for each sheet of material showing the dimensioned sheet layout for each.

*Job* prints all the *Sheets* pages as well as a page for each distinct part in the Job. If two or more identical parts are needed, it only prints a single page for the part but indicates on the page how many of that part design are required.

The *Print Labels* button prints adhesive labels for every part in the Job. Currently the system is set up for printing labels designated as 5366.

These automated drawings and layouts are designed primarily for in-house use. They require little effort to generate and contain all required information but are likely not

adequate for external use. If you need part drawings for outside use, you may need to use the *Line Drawing Editor* to develop acceptable presentations as shown to the left.

The nesting area, when combined with the *Cut List*, provides the primary manufacturing output from the software. It is intended that they contain enough information to machine and produce all the components required for the Job.

## ***Generating a Cost Sheet Report***

A *Cost Sheet Report* can be generated in the *Cabinet/Assembly Editor* as well as in *Custom Layout*. This report appears in a separate window.

When generated from the *Cabinet/Assembly Editor*, the costs displayed in the report depend on what is highlighted when the report is generated.

If an assembly comprised of two or more cabinets is loaded in the workspace and none of the cabinets are highlighted, the *Cost Sheet* reflects the costs for the entire assembly.

If one or more cabinets are highlighted, the *Cost Sheet* reflects the cost for the highlighted cabinet(s).

*Cost Sheets* generated from the *Cabinet/Assembly Editor* determine material cost using *Estimated Yield*.

When a *Cost Sheet* is generated from *Custom Layout* for either selected cabinets or an entire job, the system estimates the total number of sheets required to produce the components and adds the cost of that number of full sheets to the *Material Cost*.

We use this approach because it provides a more accurate estimate of costs. If, when determining costs for a single cabinet or assembly in the *Cabinet/Assembly Editor*, we used only full sheets, every cabinet that requires less than one sheet, regardless of its size, would have the same cost. In actuality, the single cabinet will likely be combined with others in a job where the overall yield will be approximately the *Estimated Yield*. Therefore, we use *Estimated Yield* when determining costs in the *Cabinet/Assembly Editor*.

Should a single cabinet be placed in a job, the system will revert to using the number of full sheets needed to build the cabinet. Again, this should better reflect real costs since a single cabinet may use material that cannot be used on other jobs.

When estimating costs, it is important to recognize this different approach in the *Cabinet/Assembly Editor* versus *Custom Layout*. Also, once a job has been nested, the actual material yield is automatically substituted for the *Estimated Yield* in the *Cost Sheet* as well as in the dynamic cost displays. calculating the material requirements. In truth, you really don't know your material cost until you run the nesting routine.

Prior to that point, however, you can get a reasonable guess by using a yield estimate that is close to the yield you have gotten from previous *Jobs*. This is the *Expected Yield* in the markup chart.

Once a nest has been run, cost calculations within the software switch from using *Estimated Yield* to using *Actual Yield*. The cost bar along the bottom of the display indicated to the right whether the cost is based on *Estimated Yield* or *Actual Yield*.

Once you can accurately determine *Material Cost* it is quite easy to add factors for *Labor* and *Overhead* and have the system calculate *Profit* and determine a *Selling Price*.

The final area in *Settings/Preferences* is *Standard Dimensions*. Again, this is a relatively simple area that does not require much additional explanation. It is simply a list of dimensions that will be needed when operating the program. They are entered once here so they do not need to be entered each time they are needed. You should check the dimensions for saw blade kerf and router bit diameter as these will affect how your parts are nested. If you nest using Cut Line Nesting, the system will assume you are cutting using a saw and will allow for the saw blade kerf specified here. If you nest using True part Nesting, the system will assume you are using a CNC router and will nest using the router bit dimension.

## CNC Output

eCabinet Systems software generates a CNC output file that sends information about every part needed for the job to a Thermwood CNC control system. It does not generate standard CNC code but instead generates a file that informs the control what it needs to produce. The control system then performs whatever functions are necessary to actually make the parts.

For nested sheet parts, the control performs the nesting process rather than nesting with the software in the office. Why do this at the machine instead of in eCabinet Systems?

There are actually several good reasons but they are all centered around the fact that you will know more about the production process and what you actually want to do at the machine than you will in the office. For example, you may have some partial sheets of material left from a previous job that you would like to use. You can scan these into the control and it will nest on them first. At the end of each job, the control prints a label for any material left over that is large enough to reuse so scanning the piece in is easy.

This makes using left over material easy and over a year amounts to a lot of money saved. Trying to do this from measurements in the office is clumsy at best and for most shops it just doesn't work. For example, what if you nest a job on a scrap piece and then can't find it? Nesting at the machine is just plain better.

Another plus is that the control can accept DXF output files from almost every cabinet design and CAD program and nest them with your eCabinet Systems job. This adds huge flexibility that is even better when done at the machine.

If some of your eCabinet System parts have edge profiles, the control asks if you have a custom tool that matches the profile. If you do, it uses it. If you don't, it creates a modeling program using a ball nose and flat bottom tool to model the profile.

This is a great feature when you only need a part or two and can save huge amounts of tooling money over time. It is even nice as a backup when your one and only profile tool breaks with only two parts to go in the job.

The other major advantage to creating the actual CNC programs in the control is that you can send the same eCabinet Systems CNC output file to any Thermwood CNC router and you will get the same parts even if the machines are configured quite differently.

With standard CNC programs, the program will literally run only one machine. If you need to run the same program on a second machine, even if it is supposed to be exactly the same, you need to adjust it using a post processor software package. It is not easy to exchange programs between different CNC machines.

CNC Routers are like fingerprints. They all look sort of the same but they are all really different. The approach we take eliminates the effect of machines being different and allows ecabinet Systems Members to freely send jobs to Thermwood machine owners and have them run with no hassles.

This approach is the key to Thermwood's Production Sharing program. Hundreds of eCabinet Systems Members who do not own a Thermwood CNC router send jobs to other Members with machines for processing. For more information on this program, see our web site.

## Downloading and Saving Carving Files

Carving files are available for free download from Thermwood's carving library. The Carving Library can be reached from either the Thermwood web site [www.Thermwood.com](http://www.Thermwood.com) or the eCabinet Systems web site [www.eCabinetSystems.com](http://www.eCabinetSystems.com).

Both applied and inset carving files are available in this library. See "*Adding Carvings to Cabinets*" for information about these carving types.

Each carving is downloaded as an executable (.exe) file. When this file is executed on a computer that has eCabinet Systems installed, it places the carving files into the appropriate directories so that they can be used by the software in designing cabinets and assemblies.

This same .exe file can be executed on a Thermwood CNC control and will install the CNC program files needed to actually machine the carving. Although downloading and using these files for design purposes is free, there is a rental fee associated with actually running this program on a CNC router and making the carving.

The control handles the rental fee. You purchase credits, either directly through the Thermwood control or through an office computer. If you buy carving credits through an office computer you are given an access number that must be typed into the control and the control registers with our server to keep track of credits. If you have more than one machine there is a method for transferring credits between machines.

When you run a part, the control tells you how many credits it requires and how many you have available on the control. At some point during program execution, the fee is actually charged against your account. This charge point is generally far enough through the program to uncover voids or possible problems with the material. At this point you can stop, and restart the program without additional cost. Once the charge point is reached, you need to pay the fee again to restart the program. Note that carving fees for library carvings are quite low averaging a couple dollars a part.

Applied carvings are available as either flat carvings such as a door appliqué or as rotary carving such as a leg or post. Flat carvings can be machined on any three-axis Thermwood CNC router. Rotary carvings require the optional Rotary Playback Axis. The size of the carving can be adjusted both in the software and on the CNC router.

# The Thermwood Furniture Network

## *The Thermwood Furniture Network*

The Thermwood Furniture Network is a program established by Thermwood to bring to eCabinet Systems Members the ability to customize and build professionally designed furniture in a way that allows them sell it at a high profit.

The idea behind the program is to provide to Members elements of furniture manufacturing not normally available to smaller shops and to provide these in a format that allows the furniture designs to be easily customized by each individual shop. The fact that it is “custom built” adds to its desirability and enhances the profit that can be realized from each piece.

The first element is truly professional furniture design. This can only come from true professional furniture designers. Several world renowned furniture designers have joined the program and are providing exciting designs. We plan to increase the number of available designs and the number of participating designers as the program matures.

The next element required to build this furniture is an economical method to make the myriad of complex parts, moldings, turnings, legs and carvings needed for these designs. Large furniture manufacturers spend tens and at times hundreds of thousands of dollars tooling up for a new line of furniture. Obviously this requires large production volume to justify and their traditional methods for making these parts will not work for our program.

We must economically produce essentially the same parts in single quantity without a major tooling investment. To achieve this we turn to modern technology and the Thermwood CNC router.

A CNC router can produce virtually any part using pretty much standard tooling. In most cases, you trade off the ability to make almost anything without special tooling for a longer production cycle. Custom machinery and custom tooling allows these parts to be produced faster, so large furniture companies wouldn't necessarily make them our way. However, if you only need one or two pieces, they can be economically made with a CNC router and the appropriate CNC program with little or no custom tooling investment.

Developing the CNC program can be a costly and time-consuming affair but this investment is justified if the same CNC program can be used by everyone in the eCabinet Systems program. To accomplish this we have committed to developing the required CNC programs needed to make the parts for these designs and then rent these CNC programs to Members. A fee is charged each time the program is run. This fee pays the designer for their designs and repays Thermwood for developing the program.

The Thermwood CNC control has special abilities that enhance this program including the ability to resize parts, including intricate carvings. This allows the designs to be customized and dramatically increases the value of the program.

The control also handles the rental fee. You purchase credits either directly through the Thermwood control or through an office computer. If you buy carving credits through an office computer you are given an access number that must be typed into the control and the control registers with our server to keep track of credits. If you have more than one machine there is a method for transferring credits between machines.

When you run a part the control tells you how many credits it requires and how many you have available on the control. At some point during program execution the fee is actually charged against your account. This charge point is generally far enough through the program to uncover voids or possible problems with the material. At this point you can stop, and restart the program without additional cost. Once the charge point is reached, you need to pay the fee again to restart the program.

A rotary playback axis is used to make legs, posts and turnings on the same machine.

This approach to complex parts brings incredible flexibility to small shops and makes the furniture network possible.

This might be a good time to discuss customizing. Designs offered through this program have a strong theme that can generally be applied to other applications. For example, carvings, moldings and corner posts from a dresser or china cabinet could be used on an elaborate bathroom vanity. A carved table skirt could be resized and used on a range hood. The possibilities are endless.

Since designers get paid through the CNC program rental, the more elements of their design you use the higher their fee, so we and they encourage you to use your imagination. There is one caution however. The overall scale, proportion and balance of a design are as important as individual design elements. When using design elements in a modified version, it is important to download the display files for each part resize them and build the customized design in the software so that you can see the final result. Design files and software tools are available for doing this. This process is covered in the section *“Downloading and Using Furniture Network Files”*.

The last element needed to build world class custom furniture is a world class finish. Even the best furniture designs won't measure up if you use a typical cabinet finish. Until this program, really top finishes used by major furniture manufacturers were not available to small shops.

The whole structure of the furniture industry is geared toward big companies. First, there are no standard finishes. When a major furniture company creates a new design, their designers work with the color development laboratories of the finishing supplier to

develop a finish specifically for that product. Good finishes tend to be twelve to eighteen steps and these steps can be different for every product.

Once the finish has been created, technicians from the finishing supplier travel to the furniture manufacturing plant and teach the line workers how to apply the new finish. The whole process is involved, expensive and time-consuming and only makes sense if finishing material is sold in large quantity.

In fact, since material is only sold in large quantity, major finishing suppliers literally can't blend less than several hundred gallons of anything. Their equipment simply isn't set up for it.

To address this last element, we have, working with Valspar, the largest supplier of furniture finishes in the world, established a blending facility in our plant to blend finishes in the smaller quantity needed for the furniture network.

We started by working with the designers to develop seven standard finishes (we have added eight more painted finishes and more are coming). These are quality furniture finishes with twelve to eighteen steps, blended to work in a typical cabinet shop. We have created a DVD video for the application of each of these finishes although, if you are not familiar with application of finishing material, you should attend an actual hands-on training class. We conduct formal classes to teach all the processes needed to build this furniture including the finishing process. Once you have some experience with the material, the videos should suffice for adding different finishes to your offering.

Through this program, all the elements needed for eCabinet Systems Members to build world class custom furniture are in place. For those Members who don't already have a Thermwood CNC router, there are many shops on our web site that offer to make parts for others.

Not only does this give you the ability to build truly great furniture but also to make a very high profit doing it. Typical furniture from major manufacturers is marked up from 100% to 300% before reaching the consumer. It will certainly cost you more to build this furniture than a major manufacturer with a big factory and heavy tooling investment but you do not have the same distribution markup. This means you can be price competitive and make profits unheard of in traditional furniture manufacturing. In fact, since your products are "custom" you should be able to command a price premium, enhancing profits even more.

### ***Downloading and Using Furniture Network Files***

Each furniture design is downloaded as an executable (.exe) file. When this file is executed on a computer that has eCabinet Systems installed, it places the cabinet, assembly and any component or carving files into the appropriate directories so that they

can be used by the software. At this point, the completed pieces can be accessed and built or modified. Also, the components used on these pieces are available for independent use.

This same .exe file can be executed on a Thermwood CNC control and will install the CNC program files needed to actually machine the special parts and carvings needed for the piece. Although downloading and using these files for design purposes is free, there is a rental fee associated with actually running these programs on a CNC router and making the parts. These fees are used to compensate the professional designers for use of their designs.

In addition to the actual display files used by the software and the CNC files used to make the parts, a PDF file is also part of the download. This file contains instructions for machining and building the furniture piece.

All new machines from Thermwood are set up for program rental. Machines built before this feature was available can be upgraded to add this feature.

Note that you can save considerable download time by purchasing all the files for a design as a CD that is shipped to you.

To download the files, go to the eCabinetSystems.com web site and click on *Thermwood Furniture Network*.
